Medical Sciences to all members of the medical profession in is country who wish to attend as paying participants in the conference and to the wives or other members of the families of such participants. No trouble is to be spared in ensuring the comfort id pleasure of guests, whether medical or non-medical members of e party.

CANADIAN DOMINION DAY HONOURS

he names of the following members of the medical profession ere included in a Canadian Dominion Day Honours List ublished in a *Supplement to the London Gazette* on July 1.

C.B.E. (Civil Division)

ROBERT DAVIES DEFRIES, O.B.E., Director of Connaught Laboratories, Toronto.

ANDREW HUNTER, Chairman, Standing Committee on Nutrition, Department of National Defence, Toronto.

CHARLES VEZINA, Professor of Clinical Surgery in the Laval University, Faculty of Medicine, Quebec.

O.B.E. (Civil Division)

THEODORE DEY BAIN, Director of Medical Services, Department of Veteran Affairs, Ottawa.

JAMES LYALL COCK, Halifax, Nova Scotia.

JAMES CRAIGIE, Toronto.

THEODORE GEORGE HARWOOD DRAKE, University of Toronto.

ARMAND FRAPPIER, University of Montreal.

ALFRED KIMBALL HAYWOOD, Vancouver.

GEORGE LYALL HODGINS, Vancouver.

WILLIAM JOHN KNOX, Kelowna, British Columbia.

JOHN SINCLAIR McEACHERN, Calgary, Alberta.

FRANK HASTINGS HAMILTON MEWBURN, Clinical Professor of Orthopaedic Surgery in the University of Alberta.

ISRAEL MORDECAI RABINOVITCH, Director of Metabolism, Montreal General Hospital.

NOEL RAVENCHIL RAWSON, Chesterfield Inlet, North-West Territories.

AUSTIN BIRRELL SCHINBEIN, Vancouver.

WALLACE BALFOUR SEATON, Ottawa.

M.B.E. (Civil Division)

GEORGE HAROLD ETTINGER, Associate Professor of Physiology in the Queen's University, Kingston, Ontario.

Reports of Societies

PERTUSSIS PROPHYLAXIS AND CONTROL

At a meeting of the Fever Group of the Society of Medical Officers of Health on June 14, with the president, Dr. M. MITMAN, in the chair, the discussion was opened by Dr. H. J. PARISH.

Dr. Parish said that whooping-cough, the most serious of the acute specific infections of childhood, caused at least 2,000 to 3,000 deaths annually in England and Wales, of which 90% were in the age group under five years. Dissatisfaction with the results of specific prophylaxis was indicated by the variety of vaccines and scales of dosage employed by different investigators; research was hampered by the lack of a good laboratory test. Vaccines were prepared to-day from virulent phase 1 organisms either on Bordet-Gengou blood-agar or on modified Hornbrook liquid medium (casein hydrolysate, starch, etc.). The suspensions could be precipitated with alum and washed in saline or buffer solution. Clinical evidence of the efficacy of vaccines was conflicting and often uncritical. McFarlan, Topley, and Fisher (*Journal*, 1945, 2, 205), in a carefully planned investigation at Oxford, using a British vaccine, found no significant difference between inoculated and control children. A similar trial using an American vaccine had not been completed; the results so far were inconclusive, or perhaps slightly in favour of the vaccinated group. His colleague, Mr. H. Proom, in work not yet published, had obtained low-grade pro-

tection with vaccines, made with or without alum precipitation, in mice injected with a living culture intraperitoneally. Antibacterial serum was also relatively ineffective, but antitoxic horse or rabbit serum protected mice against intraperitoneal infection. This supported the view that the death of the control mice was due to a toxin, which could be prepared from frozen and thawed, dried and ground bacilli (Evans and Maitland, *J. Path. Bact.*, 1937, 45, 715). On the other hand, the existence of some antibacterial immunity mechanism following phase 1 vaccination was suggested by a marked reduction in the number of organisms found after various intervals in the blood of mice infected by the intraperitoneal route. Unwashed phase 4 vaccines had a negligible effect. The part played by toxin in human infection was uncertain, but there was some evidence that it assisted the organisms to invade the tissues. So far no antitoxin had been demonstrated in convalescent sera, and in this respect the work of Strean (*Canad. med. Ass. J.*, 1940, 42, 525) was still unconfirmed.

When virulent *H. pertussis* was injected into mice intranasally, a pneumonia was set up; the bacteria multiplied in the lung for about 14 days and then gradually died out. The value of vaccine against this intranasal infection could be demonstrated by some increase in the survival rate of the vaccinated group of animals and by a reduction in the bacterial counts of the lung. Antibacterial and antitoxic sera also controlled the lung infection, bacterial counts being often nil. A highly potent antibacterial and antitoxic serum (horse), concentrated by Harms, was on clinical trial; the results to date in three hospitals had been disappointing. This should not have been the case if the generally accepted views on specific prophylaxis and therapy were correct.

Extensive experiments by Proom and others on mice, and the collateral clinical evidence, did not indicate that any form of specific immunization was likely to be very effective against whooping-cough. In mice the protection obtained was erratic; in man also it was variable and, at the best, of low grade, the published results being reminiscent of those observed in mice. Research on the unsolved problem of the effective control of pertussis was not made simpler by the lack of uniformity of the cases and the recognized difficulties of both clinical and bacteriological diagnoses. In no other infection were clinical trials of a preparation more time-consuming.

Need for Large-scale Investigations

Dr. W. GUNN suggested that in the past too much had been made of the administrative difficulties likely to be encountered in whooping-cough prophylaxis. He did not think it essential that the antigen must have proved its worth before large-scale immunization was undertaken. In a disease such as whooping-cough, in which infectivity was known to be very variable, and for which no reliable test denoting immunity was available, only large-scale investigation could furnish the final answer. If parents were asked if they would like to have whooping-cough antigen combined with diphtheria A.P.T. in the same injection, few would refuse. Not only were reactions no greater than after each antigen given singly, but far from interfering with each other, each might enhance the immunizing properties of the other (Lapin, J. H., *Amer. J. Dis. Child.*, 1942, 63, 225).

The only practical points of major importance were that injections should be begun at 5 to 6 months, or even earlier, instead of the more usual time of 9 to 12 months for diphtheria prophylaxis; two or three (depending on the degree of reaction to the first) injections at an interval of four weeks were given into the deltoid or vastus externus. A single injection of the combined antigen was desirable on starting school. He himself used combined A.P.T. and alum-treated whooping-cough vaccine without untoward effect, but as the inoculated group were all nursery children who shortly afterwards were transferred outside London, follow-up inquiries were difficult. For this reason standardized records, which accompanied the children, as did ration books and identity cards, were essential for a proper statistical investigation. Special examinations, such as slide agglutination and complement fixation tests, should be made at intervals on random samples of the immunized as well as of controls, as latent immunization might be a disturbing factor unduly flattering the results unless allowed for in the final assessment.

The urgent need for active immunization should not obscure the need for other measures of control. Isolation by itself could effect little, as the damage was usually done by the time the diagnosis was made, although white blood cell counts and nasopharyngeal swabs often permitted diagnosis before the onset of the whoop, but human or rabbit hyperimmunized serum might prevent or attenuate an attack in known contacts, or help in treatment in early or severe cases. Active immunization might be begun at the same time, as in diphtheria control, as shown by Downie and his associates (*Journal*, 1941, 2, 717), if the risk of the disease in a particular patient or group of patients was a grave one. In the very young the potential risk was always grave.

Dosage and Spacing

Dr. J. UNGAR said there were a number of factors responsible for the lack of confidence in this country in the value of active immunization against pertussis. Attention was now concentrated on an alum-precipitated vaccine which produced good antigenic activity in animals. Preliminary clinical trials showed that the vaccine properly administered was innocuous. An important factor in getting a proper response from pertussis immunization was the dose. The total dose recommended in clinical tests in the U.S.A., which proved successful, was in the case of Sauer's vaccine about 100,000 millions, or 30,000 to 40,000 millions for alum-precipitated vaccine. The proper spacing of the doses had a bearing on the result of immunization and the interval recommended was three to four weeks.

Another factor which allowed of a more optimistic approach was the evidence now available of the reliability of animal tests to determine (a) the virulence of the strain used to safeguard the full antigenic value of the vaccine, and (b) effectiveness of the antigenic action of different products. Some workers used mice extensively, employing either the intranasal, intratracheal, or intracerebral route for testing the effect of live cultures, and the intraperitoneal route for testing toxicity. The rabbit was a more reliable test animal, on which both components of vaccines—antibacterial and antitoxic—could be evaluated. Combined tests on mice and rabbits would help to differentiate between effective and less effective vaccines. More evidence was needed to show the part played by pertussis toxin in the pathology of experimental pertussis in animals and the usefulness of including the toxic fraction in existing vaccines. The pertussis toxin differed in some respects from usual exotoxins, and clinical proof was still needed of the value of antitoxic serum. Laboratory evidence indicated that the toxic fraction in the bacilli had a specific effect in animals which was counteracted by antitoxin.

It was now recognized that the optimal time to immunize was in the first half-year of life, preferably at the age of five to seven months, and it took about three months for the immunity to be well established, depending on the type of vaccine used and the intervals between the doses. Serum treatment (convalescent, hyperimmune, or animal) had proved its value in prophylaxis of contacts in the first six to seven days of the incubation period. In the treatment of severe cases of whooping-cough, reports were mostly unfavourable. The value of large-scale immunization was estimated by comparing the communicability rate in the immunized and the control groups and the respective fatality rates. As statistics showed that higher death rates and fatality rates occurred in more densely populated districts, test trials in the larger boroughs would help to elucidate the merits of immunization against whooping-cough. It was encouraging to read the favourable report of the Council of Pharmacy and Chemistry of the American Medical Association and the results of the pertussis immunization programme of the Boston Health Department, which indicated that prophylactic treatment conferred immunity on some children and partial immunity on others, such as might occur following whooping-cough. The incidence of pertussis was lowered after immunization with adequate doses. The attack rate was lowered in the immunized, and the disease ran a milder course.

The Ministry of Health has issued a circular on the disposal of surplus equipment held by local authorities for the Ministry's emergency services. This asks for reports on action already taken, and gives further instructions about disposal of residues.

Correspondence

Belgian Surgeons' Acknowledgment

SIR,—In May of this year the Association of Surgeons Great Britain and Ireland invited to their annual meeting a number of French and Belgian surgeons. In the name of Belgian surgeons I wish to tell our British friends and colleagues how much we have appreciated the opportunity to see work, and how touched we all were by their friendly warm welcome.

The meeting we attended at the invitation of the president, Sir Max Page, was a brilliant success from the scientific point of view. In meetings, demonstrations, and operations official and private entertainments, we made fresh contacts which we hope will be the beginning of a more intimate association and closer collaboration between our country surgeons.

The British Council, which misses no opportunity to help, had arranged to extend our visit to other centres, and on the kindness of Prof. Harry Platt of Manchester, Sir Hugh Cairns at Oxford, and Prof. J. R. Learmonth of Edinburgh we saw in these centres beautiful work of the same high quality as we had seen elsewhere.

Such stimulating visits are of the greatest possible interest for the future, and we wish formally to express our admiration and thanks, not only to our colleagues and friends, but also to the university authorities, the Royal Colleges of Surgeons in England and Scotland, and the British Council. We hope shall meet again often on both sides of the English Channel.—I am, etc.,

FRITZ ALBERT,
Professor of Experimental Surgery
University of Liège.

Population Statistics in Palestine

SIR,—I must congratulate you on the prominence you have given to Sir John Megaw's letter (June 29, p. 994) on the population of India and hope that its weighty arguments will be properly considered. As population statistics are often ignored in the following recital of events in which I played an active part at the end of the 1914-18 war may help your readers to realize how important is the information they can give.

As part of my work as medical officer in the Palestine Military Administration (O.E.T.A.) I had to introduce anti-malarial measures in my district—about a third of the country—which were later extended to the whole area. As a result of this work we were not only able to reduce almost to vanishing point the death rate from malaria but also, for the first time, to get reliable statistics of the birth rate. This proved that in some parts of the country the birth rate was no less than four times the death rate. This phenomenal condition of affairs then prevailing is by now generally recognized by demographers. What is not so generally recognized is the political implication of the phenomenon.

Largely on my initiative a memorandum was prepared for the incoming civilian administration giving definite facts and figures which showed: (1) The extraordinarily rapid natural increase of the Arab population which would certainly tax, and probably overtax, the resources of the country, and lead to scarcity and unrest. (2) That the Arabs themselves were naturally unaware of this increase and that if the immigration of Jews were allowed they would also naturally jump to the conclusion that the famine conditions were due to this extraneous increase in the population. (3) That agrarian riots were likely to follow and that these would be directed against the Jews, and the violent anti-Zionist passions would be aroused which could perhaps never afterwards be assuaged; and therefore (4) That in the interests of Jewish immigration it would be wisest to check immigration until Palestine had recovered its power to absorb more people.

I have very good reason to believe that this memorandum was actually presented to the civilian government but that the orders from London were that immigration was to go on. It did, and within two years riots occurred in Jaffa as predicted and immigration had to stop—but only when that bitterness of feeling had been generated which has poisoned Palestine and

d politics ever since. A better appraisal of the importance of population statistics which I and a few others had so fully prepared, together with an indication of their bearing on the political situation, might have changed the whole course of international relations in the Near East. I hope and pray that our politicians to-day will not display the same indifference to statistics as they did in Palestine twenty-six years ago. I am, etc.,

W. N. LEAK.

The "Intractable" Vesico-vaginal Fistula

SIR,—With reference to Prof. Chassar Moir's letter (May 18, 1944), I should like to support him in his denunciation of ureteric transplantation of the ureter as common practice for cure of urinary fistula. A point on which one has to disagree with him is his impression that fistulae can invariably be cured by vaginal operation. One disagrees in spite of his impressive triumph in curing 30 consecutive fistulae by the vaginal route. His success, however, shows what can be done. His further statement that Mahfouz Pasha¹ cured 95 of his last 100 cases is incorrectly referred to Mahfouz's, 1938 article. It is possible that Mahfouz may have made a personal statement to this effect when he gave his lecture at the British Postgraduate School; and, if this high cure rate is substantiated, Mahfouz's triumph must be unparalleled if the nature of his material is taken into account.

I have done nearly 100 operations for vesico-vaginal fistula in the Bantu, and I have at no time had more than six consecutive successful operations. Two complications which militate against success are extensive loss of vaginal tissue and loss of the urethra. Inaccessibility of the fistula can be a serious problem, but this can usually be overcome by patience. All urinary fistulae occur in the Bantu, who have usually had no trained attendant during parturition, and in the difficult case there is extensive loss of vaginal tissue that grafting is required to cover the outer aspect of the bladder suture. I have never failed to close the hole in the bladder adequately, but difficulty in bringing the vaginal edges together has led to failure repeatedly. I believe that we shall succeed now with skin grafts, and the nylon suture—even for the bladder—and local penicillin will make a 90% cure rate possible. For the average Bantu, good nursing is more important than good surgery, and in European hospitals in this country are still so overcrowded that intensive nursing care remains beyond our reach.

At the Johannesburg Non-European Hospital we have resorted to ureteric transplantation in some cases of fistula. Vaginal operation has always been attempted first, and in the cases regarded as frankly inoperable the degree of pelvic inflammation present has usually been found to preclude transplantation. Our impression is that the vast majority of cases of which colonic transplantation of the ureter is possible could without difficulty be cured by the vaginal route. In this respect, therefore, one is in agreement with Chassar Moir. But urinary fistula in the Bantu can be a formidable condition. As parturients, these women are primitive and independent, and in the conviction that death is the alternative to spontaneous delivery they persevere in labour in a manner which is unknown amongst Europeans. Fistula arises not because of some small error, as in the European, but because of a second stage which sometimes persists for days. Very severe trauma results, and this is accompanied by the pelvic inflammation which we have found present in attempting to perform ureteric transplantation.

In 1938 Mahfouz reported that Egyptian midwifery had improved and that severe labour trauma was diminishing. Even during the eight years that I have been observing these cases a change has become apparent. Bantu women living in or near towns avail themselves of midwifery services, and cases of incontinence come in mainly from the outlying country. Before the war I seldom saw a fistula case in possession of a cervix, but cases with cervix and a vagina of reasonable mobility are now frequently seen.

This indicates that the average type of urinary fistula occurring in a particular region must be assessed before operability and cure rates are analysed. Counsellor² in America does not think that these cases offer a serious problem, but analysis will show that the series in Rochester contain a high proportion of post-operative fistulae, which indeed should present difficulty

to no surgeon; Moir has had phenomenal success, but in Britain where obstetrics has reached its highest peak; Mahfouz³ cured 86.5% in Egypt in 1929, but he eliminated from his series certain cases and counted colpoceleis under his cures. In South Africa we hope to have 90% of cures in Bantu post-partum fistulae before long. I have until now considered Sims's achievement of 74% cures in 312 cases as the most outstanding in this field of surgery; but if Mahfouz cured 95 cases out of 100 he has gained the summit, for no man will cure more than this percentage of any large series of patients presenting themselves with urinary fistulae.—I am, etc.,

O. S. HEYNS.

Dept. of Obstetrics and Gynaecology, Johannesburg.

SIR,—Prof. Chassar Moir must be congratulated on his sequence of 30 cures. However, his criticism of Dr. Mackay's views (April 27, p. 650) cannot be allowed to pass unchallenged. I refer in particular to the following: "I deplore the pessimistic impression conveyed in Dr. Mackay's report regarding the curability of vesico-vaginal fistulae, and the implication that transplantation of the ureters is an operation frequently required." And, "In view of this satisfactory experience with the vaginal operation I disagree with the pessimism so often expressed."

It is obvious to those "in the know" that Prof. Chassar Moir and Dr. Mackay are discussing different clinical pictures, and anyone with experience in the Bantu native reserves will easily assess the different aspects of the problem. Over a period of ten years I have seen at least eight cases in which the only solution was uretero-colic anastomosis. This is not surprising when one realizes that "second stages" lasting three, four, and five days are not unknown.

I entirely agree with Prof. Chassar Moir that many surgeons take the easy way out and that uretero-colic anastomosis is carried out too often. It must be emphasized that transplantation of the ureters must be regarded as a sign of surgical failure as far as the fistula is concerned, and must only be used as a last resource. Three attempts to cure the fistula *without any improvement* is the earliest indication which should be accepted. With these criteria I have found it necessary to do eight transplantations over a period of six years. In the native reserves I would regard a cure rate of 75% as bordering on the miraculous, particularly in districts where the witch-doctor practises his crude primitive obstetrics.

While congratulating Prof. Chassar Moir on his excellent and very encouraging work, I must express sympathy with Dr. Mackay's alleged pessimistic outlook. This, however, must not prevent us from looking ahead, and doing all we can to improve our techniques and conditions of work, and aiming at the present apparent impossibility of 30 consecutive cures.—I am, etc.,

Non-European Hospital, Johannesburg.

P. KEEN.

Rh Factors

SIR,—Dr. Wiener's paper (June 29, 1946) will doubtless provoke comment from the experts. I only venture to write as one of the many who, though not serologists, wish to understand this theoretically fascinating and practically important chapter in human genetics, and who thereafter may wish to teach it to others. The difficulty does not lie in understanding the genetic behaviour of a system of eight or more multiple alleles, morphs, but in the fact that each gene, according to Dr. Wiener, or each compound gene, according to Prof. Fisher, determines not a single reaction but a complex and overlapping pattern of reactions. This is bewildering to those who have not become familiar with them in the course of laboratory work. I must admit that I found the story very heavy going until one day Dr. Race was kind enough to explain to me the new CDE scheme that Prof. Fisher had just devised. Illumination came almost in a flash. All the pieces of the puzzle fell neatly into place. Each gene is named according to the reactions it determines with the various antisera, which in turn are named according to the elementary antigens with which they react, anti-C, anti-e, etc., for in this matter Prof. Cappell's modification seems a desirable simplification of Prof. Fisher's Greek

letters. I have since had the opportunity of explaining the genetics of Rh, I think successfully, to medical classes as well as to individuals, and have no doubt at all of the excellence for teaching purposes of the CDE nomenclature. But when the rationale of Rh has been thoroughly grasped, facility in handling the genetic combinations makes a further step desirable—a single name for each gene complex. For these Dr. Wiener's original symbols for the antigens seem admirable, and, of course, when mastered serve as a key to the literature. It is simply a matter of knowing that, for example, R_0 is an abbreviation for the compound gene cDe, or r for the gene cde. The red cells of an individual possessing these two genes will react with anti-D, anti-c, anti-e, and also, when it is discovered, with anti-d, but will not react with anti-C or anti-E. There are not many combinations to learn and one finds that they are soon memorized.

I feel that I cannot let this opportunity pass without paying some tribute as an onlooker to the brilliance of the serological researches both in the United States and in this country. I have had the privilege of being in touch with the Galton Serum Unit since its inception and also the privilege of enjoying a most stimulating visit to Dr. Wiener's laboratories in New York. But first-hand knowledge is not required in order to appreciate the quality of the work; the published papers of the past five years speak for themselves. It would not be easy to find many instances in biological research where progress has been so rapid, where so few mistakes have been made, where there has been so little to retract, where resources have been used so fruitfully. There may be differences of opinion about nomenclature and about theory, but the concordance of the basic observations has been striking. Sometimes an advance has been due to Dr. Wiener, Dr. Levine and their co-workers in the United States, sometimes to the late Dr. Taylor, Dr. Race, Prof. Fisher and their co-workers in Great Britain; but in either event there have come almost invariably immediate confirmation and further advance from the other side of the Atlantic. Visits to this country by the American workers would be very welcome to British geneticists.—I am, etc.,

S.W.10.

J. A. FRASER ROBERTS.

The Thomas Splint

—The article by Prof. T. P. McMurray (June 8, p. 872) "Thomas and his Splint" is of great interest, but the reasons for the spectacular reduction in the mortality of fractured femur cases in the third year of the 1914-18 war are not very clearly brought out. It was not entirely the use of the Thomas splint as a method of treatment in hospitals which caused the drop in the death rate. Other splints may not have produced such good end-results, but three out of five patients treated in them did not, in consequence, die. Surely it was mainly its use as a first-aid measure on the actual battlefield which resulted in the saving of so many lives. The deaths, which were mainly due to shock, nearly always occurred on the way to, or in, C.C.S.s, and during the battle of Arras in 1917, when the Thomas splint as a first-aid appliance was in universal use, the death rates in the group of C.C.S.s behind Arras dropped from about 75% to about 20%. Indeed, the fractured femur patients arrived in better condition than those with fractured arms, and this was not surprising.

To anyone who has applied a long Liston splint in a trench, and, at a later date, applied a Thomas splint in similar circumstances, the brilliance of the idea of using the Thomas splint as a first-aid measure will need no emphasizing. Who first had this idea, or whether it was a composite proposal, I do not know, but Gray and Max Page had certainly much to do with it, and by their enthusiasm stimulated others. By April, 1917, it is safe to say, there was not a stretcher-bearer in the 3rd Army who was not an adept at applying a Thomas splint. One other factor which played an important part, and must be given due credit, in the saving of the lives of severely wounded men, was the realization that, in general, chilling meant shock, and warmth and hot sweet tea meant the prevention of shock. And so we had the folding of blankets to make three do the work of four, the hot bricks in the sandbags at the R.A.P.s, and improvised hot-air chambers at each stop "down the line."—I am, etc.,

W. STRELLEY MARTIN,
Lieut.-Col. R.A.M.C.

Control Commission for Germany.

The Catheter and the Prostate

SIR,—Mr. Wilson Hey (June 29, p. 997) raises many points which should not be allowed to pass unchallenged. He states that "there are no more misleading statistics in medicine than those in connexion with prostatectomy." In this he is quite right, and it would seem that his statistics are as misleading as any, since he operates only on the wealthier sections of the community. It is certain that his statistics would show a very different complexion had he to deal with the average type of case entering a municipal hospital (a former workhouse), dumping ground for all the crocks from other hospitals and the surrounding district.

In the prostatic clinic in the Newcastle General Hospital, transurethral resection by the cold punch is the operation of choice, the reason being that in the poorest risk this operation offers the best chance of success. It is safer than even simple suprapubic cystotomy and has the advantage that the bladder is drained by the natural and safest channel—viz., the urethra. Moreover, the operation is as near ambulatory as possible, since the patient is out of bed the day after operation and is not in any way restricted because of an abdominal wound.

I note with interest that Mr. Wilson Hey's faith in his aseptic technique does not preclude routine "preparatory chemotherapy." Perhaps his faith is like that of Col. Bramble's padre who refused to pray for rain because the barometer was too high. Moreover, he is surely not serious when he suggests that a surgeon of the experience and distinction of Mr. Winsbury White does not do his prostatectomies aseptically.

When Mr. Wilson Hey suggests that the catheter should never be used in acute urinary retention he is on very dangerous ground. It must be the experience of every general practitioner that many such cases catheterized even once recover completely and end their days without any further trouble. It is dangerous teaching that all cases of retention should be submitted to prostatectomy. It is doubly dangerous teaching when one remembers that the patient is operated upon without even being examined and consequently without the formality of an accurate diagnosis before the bladder is opened. This is surely putting the clock back thirty years with a vengeance.

Mr. Wilson Hey's figures do not in any way represent mortality rates to be expected in the community as a whole. He does not deal with the grossly neglected poor. In the year 1945 in the Newcastle General Hospital the operative mortality was 13%, but no case was ever refused operation if there was even the faintest chance of recovery. Cystotomy was never done for drainage alone. Since January 1, 1946, 164 resections have been performed, with 8 deaths, giving a mortality of 4.87%. The oldest patient was 95 years; the average age at operation 72 years; the average age of fatal cases 72.6 years. There has been no material change in technique.

No, Sir; transurethral prostatectomy has come to stay, and will in time largely replace any other form of prostatectomy yet produced. It is associated with less physical and psychological trauma than any other form of operation.—I am, etc.,

Newcastle upon Tyne.

W. E. M. WARDILL.

True Mediterranean Fever in England

SIR,—It may be of general interest to note a true case of Malta fever infection by *Br. melitensis* in this country.

The patient, a female aged 40, complained of having had a series of "chills" with slight rises of temperature for about fourteen days before seeking advice. On examination it was found that she had a mild pyrexia of 99° F. (37.2° C.), a slow pulse rate—66 a very furred tongue, and was constipated. She had a short irritating cough, and her chest showed rales at both bases, more marked on the left. She was put to bed, and on further examination nil else was found.

Her temperature then started to rise in steps, being one to two degrees higher at 8 p.m. than at 8 a.m. At the same time she suffered from intense headache, her cough became somewhat more marked, and her respirations were up to 18 per minute. Her pulse remained at 70. The highest temperature recorded was 103.8° F. (39.9° C.). After four days the temperature came down to 98.4° F. (36.9° C.) morning and night; she felt better, but had to have enemata to relieve a very severe constipation. On the eighth day her temperature started to rise again.

She now complained of fullness in the epigastrium, fainting if she got out of bed, and again severe headache. She then produced two

rigors, with increasing pyrexia, again up to 103° F. (39.4° C.). By this time my suspicions were aroused as I could find no clinical signs to account for such a marked rise in temperature. She looked typhoidal and was slumped in her bed with malar flush and a foul tongue. At this time I found she was tender to palpation in the left hypochondrium, and very tender when trying to find the spleen. A blood count showed a slight anaemia with white cells down to 4,700—polymorphs 88%, lymphocytes only 6%, monocytes 2%, eosinophils 3%, and basophils 1%. Urine: a slight trace of albumin; no pathogens.

The blood culture was negative. As I knew that the patient kept goats and milked them herself and drank the milk, I asked for a Widal for agglutination against *Br. melitensis* as well as the *Br. abortus* strain. The reaction to *Br. melitensis* was positive in only the low dilution of 1 in 25; reaction to *Br. abortus* was negative.

In view of the persistence of symptoms I made the provisional diagnosis of Malta fever and arranged with the M.O.H. for the goats to be tested. One goat had aborted six months ago and had been mated again. It did not produce kids, but did produce milk. This goat has now been found to be strongly positive to agglutination with *Br. melitensis*. The other goats in the small herd remain to be tested.

I believe this to be the second recorded case of infection in goats in this country. In view of the fact that, during the war, goat-keeping has increased by leaps and bounds for milk production, I consider that all goats used for milking should be tested once a year, and the owners registered.—I am, etc.,

Christchurch.

E. F. HUNT.

Placement of the Disabled

SIR,—May I correct one point in your excellent leader of May 25 (p. 803)? The Act states that anyone who is physically or mentally handicapped is "to be put on the Register"—irrespective of whether he is doing suitable work or not. I understand that of the half a million people already registered the vast majority were actually in satisfactory employment at the time of registration.—I am, etc.,

Bedford.

E. N. GRAHAM.

Shock Treatment of Bronchial Asthma

SIR,—Dr. E. Brauer's 1939 article on the above subject has travelled afar among medical friends and colleagues, yet has, though now tattered and torn, luckily always come home. It was a pleasure to see his return to print (June 1, p. 849) on the subject.

Administration of the contents of the ampoules is simplicity itself, and, in the small number of cases available here, not the least untoward action has been observed. For twenty-four hours the patient feels as if he or she has had a bad attack of influenza—nothing more. Out of 15 cases only one failed to show improvement. The rest have been, less or more, encouragingly benefited. The three earliest cases may perhaps be quoted, with a minimum of detail.

A miner aged 50, typically asthmatic for twenty years, had been off work for five years. Following the publication of Dr. Brauer's article, the patient was given a dose of "pyrifer" in September, 1939, another in November, and in late January, 1940, he asked for another dose "to clear me up for work." Following this he worked continuously for two and a half years till he died of pneumonia.

A youth aged 20, very keen to join the R.A.F. in 1939, despite the fact that he had been subject to asthma for eight years. Naturally he was "turned down in his medical" because of his chest condition. Two doses of shock treatment cleared him up astonishingly, and he asked for a third one, just before volunteering again, ten months after his first board. He was passed Grade I and was quite free from any breathing difficulty during his time in the Air Force. (This may of course be put down by the sceptical to Service conditions.) One slight attack came on while on long leave following a fractured femur, but he had another dose and has been quite free since.

A lady school teacher aged 25, asthmatic from 12 years of age. Two doses in 1939, and required no more till staying with friends in 1943. Her then medical attendant told her that "neither I nor any other medical man can do you much good." Her brother motored down for a further dose. Had she been at home she would have received the third strength, but, as the M.O. was very doubting, a repeat of No. 2, and Dr. Brauer's article containing full instructions, were sent. Reaction was, in this case, somewhat delayed but no further treatment has since been called for.

A woman aged 55 (patient of a colleague who asked me to give "pyrifer"), troubled with asthma "all her life," showed no improvement whatsoever following two doses of No. 1 and one dose of No. 2. She reacted all right but nothing more.

Such, Sir, are reports on four cases treated in this practice by the "shock treatment for bronchial asthma." In another 11 cases the results have been more than encouraging, yet, with such a meagre number to go on, one felt diffident about rushing into print. But, as Dr. Brauer has returned to the subject, it is to be hoped that he will now give to the profession a summary of the results obtained in his so much fuller experience. The subject would appear to be one which calls for widespread investigation and trial. So far as this practice is concerned, both patients and G.P. desire to express to Dr. Brauer their thanks for bringing to their notice a method of treatment which has yielded most acceptable results.—I am, etc.,

Kirkcubbin, Dumfriesshire.

BOWMAN EDGAR.

National Research into Tuberculosis

SIR,—I agree with the various writers on the need for such research. I agree with Dr. J. St. P. Cowell (June 22, p. 964) that the matter concerns every medical man, but I do not think the profession should be so greatly blamed. There is a greater need for public interest in the means of prevention and treatment. The practical aspect comes to the erection of an Institute for Tuberculosis Research. Why wait for the Government? Why should the profession itself not create the Institute, and appeal also to the public? Let it be the medical profession's institute for tuberculosis research. Without further ado I am willing to receive a simple statement of support to the proposal and a willingness to subscribe towards the project some sum (nothing more at present). If the proposal and amount that would be subscribed is evidence of substantial support within a month I could then advise all the supporters and find out when they could meet to decide all necessary steps.—I am, etc.,

Blyth, Northumberland.

A. G. NEWELL,
Medical Officer of Health.

Migrainous Headaches

SIR,—I have read with considerable interest Dr. Wilfred Harris's paper on migrainous headaches (May 18, p. 754) and Mr. Cecil Tivy's letter (June 22, p. 964). I agree wholeheartedly that frequently migraine is not given either the sympathy or treatment it deserves. Patients are, in general, classified by their practitioner as incurable—and so informed!

In a large number of cases this is not true; many can be relieved by a combination of endocrine therapy, desensitization with prostigmin, or the ingestion of urea in varying doses. Such therapy, to be successful, must be applied with knowledge and persistence; but it is far less drastic than interfering with the Gasserian ganglion and, one feels, should be tried in all cases of true migraine before irrevocable methods are undertaken. This treatment has the advantage of doing no possible harm; while gratifyingly often the patients, to their surprise and intense relief, if not completely cured, are at least enabled to look forward to a tolerable future.—I am, etc.,

London, W.1

NEVIL LEYTON.

Effect of Sweets on Teeth

SIR,—My attention has been drawn to the letter from Miss Dorothy M. Richardson (June 29, p. 1010) criticizing my study of the effects of boiled sweets and chocolate biscuits on dental caries activity, cited by Dr. H. E. Magee in his Milroy Lectures. As stated in my original paper (*Lancet*, 1946, 1, 646), both sweets and chocolate biscuits were given to counteract this type of criticism. The composition of the latter was as follows:

Biscuit.—Wheat flour 48.8%; total sugar 24% (reducing sugar 3.25%); fibre 7%; fat 17.2%; water 3%. The "reducing sugar" consisted of glucose, laevulose and maltose.

Chocolate.—Sucrose 43.5%; fat 32%; cocoa solids 24.5%.

I can assure Miss Richardson that the biscuits, at least, were certainly not "non-adhesive." Both chocolate and biscuit portions remained in the tooth fissures and interdental spaces for a considerable time.

In addition, the children were given their usual sweet ration, in which chocolate cream and fudge were included, while their general diet contained more than 50% of carbohydrate in the form of sugar, jam, bread, potatoes, oatmeal and breakfast cereal.

Finally, I would refer Miss Richardson to the *British Medical Bulletin* (1944, 2, 225) for a brief account of some of the fundamental reasons for questioning the validity of the carbohydrate-fermentation theory of dental caries.—I am, etc.,

London, S.E.5.

J. D. KING.

Book Reviewing

SIR,—Is it not time the *B.M.J.*—and indeed other medical journals in this country—conformed to the practice of their contemporaries in other literary fields in publishing the names of book reviewers? I presume that you endeavour always to enlist the services of an expert on the subject-matter under review. But how are your readers to know this? The position at present is that magisterial and pompous comments are sometimes made by reviewers who may or may not be experts (so far as we know), and who are able to indulge their preferences and prejudices, if not indeed a little personal malice, under the cloak of anonymity. I am not suggesting that indifferent work should be condoned; any more than that writing for the sake of writing should be encouraged. But let us have the reviewer's name. We can then judge *how* "expert" he is; we can, if necessary, challenge his criticism, and we can give ourselves the mental exercise of assessing the relative merits of author and reviewer!

It is not easy, I know, to write a balanced review. It is perhaps a help to be thoroughly familiar with the author's training, his intellectual ability, and his clinical day-to-day work. This is unfortunately not always possible. One is so apt to allow judgment to be influenced by such factors as personal prejudices for this or that method of treatment, or this or that method of presentation of a subject. But I think it is important to try to be objective, to be helpful both to the author and to the public, and to avoid harshness. In the past year or so I have felt that some orthopaedic critiques have been scarcely fair either to potential readers or to the author—few shared with me by many distinguished orthopaedic surgeons. I will mention one example. A book on *Injuries of the Knee-Joint* has recently been written by Mr. I. S. Smillie, founded on a war-time experience of some 5,000 patients with complaints directly related to the knee-joint. In a modestly worded preface Mr. Smillie explains the background of his book and the difficulties under which it was written. He is careful to make no extravagant claims—and this admirable principle is followed throughout the book. Having had the privilege of seeing much of Mr. Smillie's work during the war, and accounting it *on results* (in terms of fitness for return to military service) as easily among the very best accident surgery in Britain, I read his book with a real knowledge of the man and his work. Though I do not agree with all his opinions, I find the book most stimulating and informative; I made haste to present copies to some visiting foreign colleagues; and I consider that another valuable monograph has been added to my orthopaedic library. There are, of course, faults in the book, but is there any book in which to someone's way of thinking there are no faults?

A review of this monograph was published in your edition of June 1. It reads like a Victorian headmaster's address to his pupil, or a would-be dictator to his underlings. It is patronizing, pompous, and in my view quite unjustifiably censorious. Amongst other alleged vices, Mr. Smillie is taken to task for lack of proper statistical analysis. The reviewer, a few sentences later, refers to one of Smillie's operations as "a procedure of dubious value," but he (the reviewer) quotes no statistics of his own to support his pontifical dubiety. We are assured towards the end that two of our colleagues are neither anatomists nor physiologists. Is this true even if it is relevant?

I find it hard to believe that a book review which concentrates only on the faults, or in the opinion of the reviewer the faults, is helpful to anyone. An anonymous public arraignment of this type must be discouraging to any author of any age who has worked hard and thought much, and who has produced a book which many of us value. Fortunately Mr. Smillie has

the ability and the resilience not to be unduly perturbed. But how much better it would have been if your reviewer had been more restrained—and he probably would have been if he had had to append his name. A personal letter of friendly criticism to the author would, I am sure, have been welcomed as a help in improving the book for its next edition.

Another point—unless the names are appended how do we know that the *B.M.J.* is not selecting reviewers who, in the words of Prof. Robert Platt (*Manchester Guardian*, June 1), when referring to the gentlemen recommended by the British Medical Association for the recent elections to the General Medical Council, "are best qualified to represent the views of those who have already retired from practice"?—I am, etc.,

Manchester.

H. OSMOND CLARKE.

Rectal Cancer in Sisters

SIR,—We should like to reply to Prof. M. Greenwood's letter (June 22, p. 965), in which he criticizes our own of May 25 (p. 814).

Prof. Greenwood takes us to task for commenting on the statistical conclusions that Dr. R. E. Rewell attempted to draw from one quoted case, and this he does on the grounds that Dr. Rewell's hypothesis was reasonable. Nowhere in our letter did we criticize this hypothesis, and our remarks were directed solely towards drawing attention to the danger of misusing statistical methods (and, more especially in this case, statistical jargon), as evidenced in the last paragraph of Dr. Rewell's communication. Prof. Greenwood himself has been moved to write: "Medical papers now frequently contain statistical analyses, and sometimes these analyses are correct, but the writers violate quite as often as before the fundamental principles of statistical or of general logical reasoning." (*Lancet*, June 11, 1932). Dr. Rewell had indicated that from the evidence he adduced a probability could be assessed for his hypothesis, and the impression was certainly given that this probability exceeded one half. In fact, no such probability could be calculated from the data, and it seemed reasonable to point out, especially in a journal catering for non-mathematical readers, that the statistical support claimed by Dr. Rewell was, to say the least, somewhat flimsy, and not such as to warrant any confident conclusion.

In fact, as Prof. Greenwood implies, the *a posteriori* probability would only warrant entertaining the hypothesis if the *a priori* probability were appreciable—a point which few readers can be expected to have grasped. It would therefore appear to be of value to consider the *a priori* probability in the actual cases quoted by Dr. Rewell. It may be recalled that the original article concerned two sisters—one had multiple telangiectases, the other multiple polyposis, and both died young of carcinoma of the colon. There is no recognized connexion between multiple telangiectases and carcinoma of the colon, or between multiple telangiectases and multiple polyposis, and the article contains no recorded cases showing a connexion. Yet in spite of this, and without any argument from general pathological principles, the author states: "Carcinoma of the rectum in siblings of this age is so rare that one must conclude that there is some connexion between the three conditions." (Italics our own.) This has nothing of the tentative nature of the statements that Prof. Greenwood attributed to Dr. Rewell.

We do not believe that Dr. Rewell forbore to comment on our letter because he was reminded of Bacon's essay, "Of Seeming Wise," but we are constrained to ask who it is who "seems too wise." Prof. Greenwood has answered that question better than we could do: "... it would be silly to ... proclaim that his [the doctor's] intimate knowledge of the facts puts him above the reach of those vagaries of chance which 'mere' statisticians emphasize." (*Journal*, Jan. 26, p. 119).—We are, etc.,

London, N.W.8.

P. J. HILTON.
S. M. HILTON.

The Hypochondriac's Treatment

SIR,—Dr. E. D. Granger (July 6, p. 27), who so mildly rebukes Dr. Summerskill for her reported remarks, is in my opinion perfectly correct. I would perhaps have been a little harder. A so-called malingerer whom I recently had as a patient died

a few months later from prostatic carcinoma. He had been thus labelled because of his whining complaints and the vagueness of his symptoms. His complaints were chiefly of flitting and sometimes severe pains in the bones, especially in his spine in the lower lumbar and sacral regions. I managed to elicit a fact which the specialists in the hospital had overlooked or had not noticed—i.e., a definite frequency of micturition, especially during the night, and as he was a man of 60 I began to suspect the prostate was diseased. Although he had been x-rayed in hospital it had been a little early to pick up the tell-tale deposits in the spine and pelvic girdle, but an x ray taken by myself and only a month after leaving the hospital revealed the true nature of his "hypochondria," for he died from the disease less than two months later, relieved from his very acute suffering only by large doses and continuous administration of morphine.

In my ten or eleven years of experience of general practice I have come to respect the feelings of patients the more and I have learnt not to dismiss their condition as "just another case of neurosis" without a very thorough search into the whole case-history and a still more thorough examination of the patient. In any event, under the stress of modern life the nervous system of the individual is subjected to strain his forbears had rarely to bear, and the fact that some of us become hypochondriacs is not surprising, and indeed they are people much to be pitied and people who should be most carefully handled. The handling of them is a skilled job requiring much patience. It is not surprising that many doctors simply shirk the job.

Dr. Summerskill's remarks bear not a little trace of the doctrines of Nazism, for it is not a very long jump from the trend she desires in the treatment of the hypochondriac to the purification of the race by the forced segregation of misfits and their quiet removal from the world as carried out only too efficiently under the Hitler regime. Perhaps she does not see the dangerous road along which her socialistic beliefs are driving her.

How much we doctors prize our present freedom of thought and action in the carrying out of our duties! How much we are likely to kick under the dictation of a more and more autocratic system of government we may learn when it is too late and long past worrying about. There is no use pretending, for we are in a trap from which there is no escape, and that trap is largely of our own making, because if from the inception of the so-called negotiations preparatory to the introduction of a State scheme of medical practice we had stuck to our guns and had nothing to do with a system of medical practice which the majority of us are going to detest, we could have fought against its introduction the better. But we compromised and accepted in part, and when the softening-up process was in an advanced stage under the Coalition Government it was the easier for Mr. Bevan and his satellites to press further and more drastically and even to drop the pretence of negotiation. One has only to read the weekly reports of the Committee stage of the Bill to realize how far-reaching will be the effect on the lives of all doctors of its passing into law.—I am, etc.,

Strathpeffer.

KENNETH I. E. MACLEOD.

Health Service Bill

SIR,—Mr. G. H. Urquhart (July 6, p. 26) states an admirable case. I have just attended a local meeting of the Labour Party, sponsoring a "medical brains trust." Factual ignorance, overweening self-assurance, desire for domination, and disease-consciousness were well marked; class-consciousness was present in the trust. Salesmanship was good, the particular line for the day being group practice in health centres with doctors working in shifts and maintaining a high standard of efficiency under mutual supervision!

The immediate corrective to adopt, for those of us who believe the above symptom complex to be of bad import, is quite clear. Broadcast the objects and powers of the B.M.A. (see Constitution). The Association was formed "to promote the medical and allied sciences, and to maintain the honour and interests of the medical profession." In emphasizing the words in italics the major part of the *British Medical Journal*, the six quarterly journals, and some thirty publications, entirely non-medico-political, should not be forgotten, nor should

the Association work on fractures, physical education, first-aid training, and hospital planning, etc. These things and the B.M.A. policy on the present Health Service Bill should be kept daily before the public eye through the public relations committees, the Press, and the political parties now in opposition. If we all lend a hand and keep it up we shall win the battle for independence.—I am, etc.,

Birkenhead.

R. W. L. PEARSON.

Powers and Procedure of G.M.C.

SIR,—It is with much interest that the profession will read of the suggested reforms of the powers and procedure of the General Medical Council which have been drawn up by the three defence bodies (July 6, p. 21). It is not before time, and I am sure without exception that the profession will welcome a "trial" before a body which will carry out its judicial work in accordance with the observance of the rules of procedure, etc., as administered in the other courts of law. While these suggested reforms as put forward are indeed excellent, there are in my opinion one or two matters which have been overlooked.

In the first place there ought to be allowed to a doctor legal representation at all proceedings where the doctor's professional conduct is under review. At the present time, when a medical man who has had his name erased from the *Register* applies for reinstatement, the procedure is at present that he makes his application for such in writing. This is considered by a committee without either hearing him or allowing him to be represented by an advocate, and in due course their decision is communicated to him, or they may call upon him to appear, but I understand that as it is at present the doctor cannot appear by an advocate. It is well known that the presentation of any case sounds entirely different if the defendant appears either in person or, better still, if he appears with counsel.

Next I would advocate that the rules of evidence be strictly adhered to. All hearsay and other evidence not received in our other courts be excluded. I would suggest the time in which a notice of appeal can be lodged be extended to fourteen days instead of seven as at present suggested. The right of appeal should not be confined to one on a point of law alone but should be allowed on similar grounds as allowed in the other courts. Further, I would suggest that the legal assessor be a barrister who also has a medical degree, of whom there are several practising law. Or, alternatively, a chairman with the dual qualification be appointed who would be able to control the proceedings. This chairman need not be a permanent appointment, and would merely act as legal assessor and refuse or admit evidence according to law, etc., etc. He would not be a member *ex officio* of the council.

All documents for or against the doctor charged should be proved, and "notice to produce" but not "to admit" should be permitted. The tribunal to decide if the document is a privileged one. If a charge is found not proved costs against the complainant should be awarded, and such costs should be recoverable as in civil law. Besides erasure and censure, as at present permitted, the tribunal should have power to impose a fine if they were of the opinion that such would meet the case. At the present time a lesser tribunal—a panel committee—has power to fine a medical man for "over-prescribing."

I, fortunately, have never been before the General Medical Council, but while practising medicine I always felt that if ever such should be my fate I would writhe at the thought of being "tried" by a body of laymen who sat as a judicial tribunal and whose procedure was different from that of a court of law.—I am, etc.,

Temple, E.C.4.

C. J. DE VERE-SHORTT, M.D.,
Barrister-at-Law.

SIR,—It is possible to swing the pendulum to the other extreme and claim, as some have done, that if the Hennessy case had been tried in the first instance before a judge and jury all would infallibly have gone well for Dr. Hennessy. Mr. Justice Humphreys in a very recent book entitled *Summing Up* (extracts published in the *Sunday Graphic*) has given instances of miscarriages of justice, indicating that these errors are most likely to occur when perjury is committed by a woman alleging sexual offences or the distribution of obscene libels.

In the Swan v. Gooding trials, Miss Swan completely took in three juries and at least two judges (Mr. Justice Bailhache and Mr. Justice Avory). Mrs. Gooding was sent to prison, and for this miscarriage of justice the Treasury paid £250 in compensation to Mrs. Gooding when the two convictions were quashed on July 26, 1921. I quote from Mr. Justice Humphreys' article in the *Sunday Graphic* (March 17, 1946).

"In the restricted circle in which she lived and moved, Edith Swan was a real public danger. Are we then to understand that such a woman can by ingenious perjury bring about a serious miscarriage of justice as and when she pleases? Are innocent people in real danger of being wrongly convicted through no fault or omission on their part, but according to the whim of a mentally unbalanced female? I think not, though I should be sorry to prophesy that such a case will not occur again, as in truth it has happened before."

It has occurred again in the Boyanton v. Hennessy case before the G.M.C. It occurred in the past in 1912, and again in 1913, when Mrs. Johnson of Redhill was twice convicted and sent to prison for sending letters of a threatening and obscene nature to a Mr. and Mrs. Woodman, Mrs. Woodman being in fact the source of the libels and a ready perjurer. Here again the Treasury awarded Mrs. Johnson £500 compensation when Mrs. Woodman was eventually convicted of perjury and other offences in February, 1915, and sentenced by Mr. Justice Horridge to eighteen months' imprisonment. (*Sunday Graphic*, May 5, 1946.)

Why did the G.M.C. go astray in the Hennessy case? It is not enough to say that the doctor should have provided additional evidence in order to save himself. Mr. Justice Humphreys' comments on the Gooding case are worth quoting as they are applicable here:

"The case of Mrs. Gooding, always more or less in my mind for twenty-five years, has hardened into a principle which I found rather vaguely expressed in the books I read as a pupil—namely, that it is too dangerous to accept as satisfactory evidence upon which to convict in any sexual case the statement of the woman concerned unless there is other evidence tending in the same direction. Further, that this rule should never be relaxed merely because the prosecutrix in the witness-box behaves like an angel and looks like a madonna."

This is the first lesson to be relearned from the Hennessy

It should, I think, be inscribed on a plaque somewhere in reserved for trials, where the jurors and judges can their memories. The second lesson is that no compensation has been paid to Dr. Hennessy for the miscarriage of justice he suffered at the hands of the G.M.C. May one add another invocation to the well-known *Doctor's Litany*,

"From forgetful judges, glibbie juries, and hasty G.M.C.s,
Save, O Lord, us poor M.D.s."

—I am, etc.,

Slough.

N. C. HYPER.

Re-education of Germany

SIR,—Some of your readers may have read with the same sense of indignation as myself the statement recently published in the *Times* that a German physician in the British Zone has just been sent to prison for a year "for failing to stand when the British National Anthem was played at the conclusion of a concert." I do not know this doctor. I do not know whether he was a Nazi, or whether he was a credit to his profession, but it seems to me that a sentence of this kind ought not to go without some expression of protest from the British medical press. I do not mean by this that the fact that the accused was a doctor entitles him to special privilege, but rather that because of it this lunatic sentence may bring home to us a little more cogently the sort of thing which is being done in our name. Medical men have had a good deal to say about the re-education of Germany: if this is how the responsible authorities consider that re-education can or should be conducted, perhaps it is time that they were more intelligently advised. Faced with a problem of public health, they have acted on the whole competently and creditably. If the goodwill accumulated by those means is to be dissipated at the psychological level by actions as stupid and as reminiscent of Hitler himself as this one, perhaps we have a duty to criticize at least as forcibly as anyone else.—I am, etc.,

LeaJen, S.E.23.

ALEX. COMFORT.

Obituary

T. IZOD BENNETT, M.D., F.R.C.P.

The sudden death of Dr. T. Izod Bennett, which took place at his home in Hill Street, Mayfair, on July 10, on the eve of his fifty-ninth birthday, removes a figure of much originality and distinction from British medicine. He might well have looked forward to several more years of achievement. His work, especially at the Middlesex Hospital and the Royal National Orthopaedic Hospital, the two principal institutions he served as physician, was highly regarded by his colleagues; he was a recognized authority on disorders of the alimentary tract and on metabolism in health and disease; as a teacher he was unusually gifted; and he was the author of many books and papers which bore the impress of a careful and logical mind.

Thomas Izod Bennett was born in July, 1887, at Christchurch, New Zealand, and was educated there, coming to London for his medical training, which he took at Guy's Hospital. He qualified in 1912 and graduated M.B., B.S.Lond. in 1914. After holding various house appointments at Guy's, he joined the R.A.M.C. at the outbreak of war in 1914, and served on the Western Front for two years as medical officer to the 8th Battalion of the North Staffordshire Regiment. Later he was physician to No. 54 Casualty Clearing Station, holding the rank of major. After the armistice he returned to Guy's as medical assistant and demonstrator in physiology, a post which permitted him to resume the researches in internal medicine which had been interrupted by his war service. In 1920 he took the M.D. of the University of London and in the same year became M.R.C.P. He was elected to the staff of the Middlesex Hospital as physician with charge of out-patients and as tutor to the medical school. He was now well established in private consulting practice. In 1921-3 he held a Beit memorial fellowship for medical research. In 1928 he was Goulstonian lecturer to the Royal College of Physicians, of which he had meanwhile become Fellow. His subject was "Some Problems of Nephritis," and the lectures were subsequently printed in book form. He was dean of the Middlesex Hospital medical school from 1929 until 1934.

Other posts which Izod Bennett held were those of senior physician to the Stoke Mandeville Hospital, consulting physician to the Cane Hill Mental Hospital (L.C.C.), St. Columba's Hospital, London, the Faversham Hospital, and St. Luke's Hostel for the Clergy. He served as examiner in medicine for the University of London, and later, from 1940 to 1944, for the Royal College of Physicians. He was a prominent member of the Association of Physicians and a frequent contributor to its proceedings. For over a quarter of a century he belonged to the Medical Society of London and the Royal Society of Medicine, and he was President of the Section of Medicine of the latter body during the session just closed. One of the characteristics of Izod Bennett, observed alike in his writings, in medical discussions, and in the lecture theatre, was the carefulness and precision of his language. He was impatient with anything slovenly in the presentation of facts or ideas; he would not tolerate it in his students or in himself, and his contributions, even the slightest of them—even a few remarks on the spur of the moment—were models of logical thinking and expression. He was the author of numerous books and papers dealing mostly with alimentary and renal physiology and pathology. His first considerable literary work, on the stomach and upper alimentary tract, appeared in 1925; a small book by him on the treatment of

HECSON

SUPER ELASTIC TRUSS

for the Treatment of Hernia

Where treatment of Hernia by surgical methods is undesirable for any reasons, the HECSON super elastic truss can be confidently recommended. The Special Feature of the HECSON Truss is that the perineal or under strap is attached to the top of the pad instead of the lower margin as in the ordinary elastic or old spring truss. Thus it becomes part of the leverage mechanism for increasing the pressure of the pad at its base.

Price: Single £2 5s. 0d.
Double £2 19s. 6d.

Further particulars on request from
the manufacturers

Strap is fixed to Pad at A.
Therefore greater pressure
is exerted at B, when the
strap is pulled tightly.

A non-greasy

ANALGESIC OINTMENT

Relief of pain and discomfort within a few minutes and lasting two hours or more is obtained after the simple, direct application of 'Anethaine' Ointment to the skin or mucous membrane.

'Anethaine' Ointment is non-greasy and is readily removed with water from the skin or clothing. It contains 1.0 per cent. of the fat-soluble base of amethocaine hydrochloride.

For the relief of pain in haemorrhoids and skin diseases generally. Many other uses will suggest themselves to doctors.

brand

PETHIDINE HYDROCHLORIDE B.P.C.

Pethidine Hydrochloride possesses analgesic and antispasmodic properties, and is used with success in midwifery. It is especially valuable where prolonged labour is due to cervical spasm.

Pethidine Hydrochloride may be employed to alleviate pain in renal, intestinal and biliary colic, in hypertensive headache, and in neuritis of diverse origin. It may be safely administered in therapeutic doses by the oral and parenteral routes with minimal risks of habituation. Technical literature and further information will be forwarded on request.

PACKINGS

Tablets of 0.025 gramme and 0.05 gramme in bottles of 25, 100 and 500.

Ampoules of 0.05 gramme (1 c.c.) and 0.1 gramme (2 c.c.) in boxes of 10 and 100.

Solution in bottles of 25 c.c. (each c.c. containing 0.05 gramme).

Obtainable from your usual suppliers.

Ph.133

diabetes appeared in 1931, and he was a frequent contributor to the medical journals.

Izod Bennett was known to his friends as a man of most kindly disposition who curbed natural irascibility under a calm manner. Thorough and methodical in going into a case, he never forgot that the patient was a person in need of help and sympathy. Colleagues who came under his professional care will recall his thoughtful study of symptoms in relation to their background and his unobtrusive acts of good nature. He spoke French fluently and knew Spanish, and often put himself out to entertain medical visitors from the Continent. His indoor recreation was a rubber at bridge before dinner, and the fellow-members with whom he regularly played in the card-room of his club noticed with much concern that his health was failing in recent weeks.

Dr. DOROTHY MANN ADAMS, who served with distinction in the R.A.F. Medical Service during the war, died very suddenly on June 27. She was born on Dec. 13, 1903, studied medicine at Oxford and at King's College Hospital, London, taking the English Conjoint diplomas in 1929 and the B.M., Ch.B. degrees a year later, after holding the post of house-surgeon at the Royal Victoria Hospital, Folkestone. Dr. Dorothy Adams had been medical inspector at Cheltenham Ladies' College before joining the R.A.F. with the relative rank of flying officer early in 1940. She was gazetted war substantive flight-lieutenant in April, 1941, and temporary squadron leader in July, 1943, and was mentioned in dispatches.

The death of Dr. EDWARD BAINES took place at his house in Whitby, Yorkshire, on June 28, at the age of 80. He was the elder son of J. W. Baines, of Leeds, and was born in that city in 1866. From the Leeds Grammar School he went up to Caius College, Cambridge, and took the M.B., B.Ch. of that University in 1892. After graduation he was for a year H.S. at the General Infirmary, Leeds, and for another year H.P. at the Sunderland Infirmary. He first practised at Bowness, Windermere, but after a severe illness a few years later took up public health work and received the D.P.H. Cantab. in 1902. Later he returned to general practice, settling in Whitby in 1906, where he was for many years a member of the medical staff of the Whitby and District War Memorial Hospital and its predecessor. In 1936 he had another severe illness and was thereafter obliged to limit his activities. However, when his son, Dr. E. F. Baines, who had joined him in practice, left Whitby for war service in 1939, Dr. Baines resumed full work, but broke down once more in November, 1940: he had also been serving on the Scarborough Civilian Medical Board. He married in 1900 Miss Adeline Fyfe, who died in 1944; there was one son and one daughter as issue of his marriage. Dr. Baines was a member of the B.M.A. from 1893; but never sought office in the local division. He was a regular supporter for many years of the Royal Medical Foundation of Epsom College.

Dr. THOMAS STRETHILL WRIGHT, who had practised at Okehampton, Devon, and held public appointments there, died on July 1 in retirement. He was born at Hartford, Cheshire, on Dec. 5, 1879, son of S. H. Wright, M.D., F.R.C.P., and was educated at Monmouth School and Brasenose College, Oxford, where he gained classical honours and graduated M.A. in 1906. He then entered St. Thomas's Hospital and obtained the M.B., B.Ch. degrees at Oxford in 1909. He held a temporary commission as captain, R.A.M.C., during the 1914-18 war and at the end of it proceeded M.D. Dr. Wright joined the B.M.A. in 1910 and published notes on trench fever in this *Journal* in 1916. After giving up active work he lived at Prestbury in Gloucestershire.

We regret to announce the death at Beaulieu, Inverness-shire, on July 4 of Dr. RODERICK MACKAY, who was elected chairman of the Inverness Division of the British Medical Association in 1938. Dr. Mackay was born on Jan. 23, 1900, and studied medicine at the University of Aberdeen, graduating M.B., Ch.B., in 1924, and M.D. with Commendation in 1928, after serving as house surgeon and house physician at the Royal Northern Infirmary, Inverness. While in general practice at Beaulieu he was medical officer to the Kiltarlity and Array parishes and a member of the Inverness and Ross County Panel Committees. He joined the R.A.M.C. with a temporary commission in January, 1940, and was captured by the enemy on July 10 of that year. His name was brought to notice in recognition of distinguished services and he was repatriated at the end of 1943.

Dr. A. DOUGLAS CROFTS, of Windsor, who died on July 7 after a short illness, studied at Guy's Hospital and, after taking the L.D.S. in 1903, completed the medical curriculum and qualified as M.R.C.S., L.R.C.P. He then held a succession of house appointments at Guy's and was clinical assistant at the East London Hospital for Children and at the Evelina Hospital for Sick Children. During the 1914-18 war he served with a temporary commission in the R.A.M.C. Dr. Crofts held a number of important posts in the Windsor area; he was a member of the Eton College Medical Board, M.O.H. and school medical officer for the borough of Windsor, honorary anaesthetist to the King Edward VII Hospital, and medical referee to the Ministry of Pensions; he was also medical officer to St. George's School, Windsor, and to a number of infant clinics. He joined the B.M.A. in 1912, and had been vice-president of the Windsor and District Medical Society.

We regret to announce that Dr. FRANCIS WILLIAM SCHOFIELD, J.P., died at his home in Bramwell Lane, Stockport, on July 7. He was born at Mossley 65 years ago and studied at the Manchester Medical School, taking the M.B., Ch.B. Vict. in 1902, and a few years later the M.B., B.S. Lond. After qualification he worked as house-surgeon at the Bradford Royal Infirmary, ophthalmic house-surgeon at the Sheffield Royal Hospital, and assistant medical officer at the City Hospital, Sheffield. He had practised at Stockport for nearly 40 years, and at the time of his death was senior honorary surgeon to the Stockport Infirmary, having joined the staff in 1925. During the war of 1914-18 he served with the R.A.M.C. in France and Egypt. Dr. Schofield joined the B.M.A. in 1910, was assistant secretary of the Stockport Division for five years, and chairman for two periods of five years; he was also chairman of the local Medical War Committee and of the recruiting board, and a member of the Panel Committee, and since 1937 had been a magistrate on the Stockport Borough Bench.

His many friends and patients will learn with regret of the passing of Dr. ILJA MARGOLIN, of Hall Green, Birmingham, at the age of 54. Born in Russia, he was interned in Germany during the first world war, and in his early days was a surgeon. Subsequently he established himself as a consulting physician in Berlin, until the advent of Hitler made him a refugee. He qualified in this country and set up as a practitioner in Birmingham. A. W. and S. L. write: His great knowledge, impressive appearance and personality drew many patients from all parts. His house was always a haven of rest for the victims of Nazi persecution. In 1942, in spite of his age, he joined the Forces and was invalided out in 1944. Thereafter he suffered much, but endured with truly marvellous courage. His philosophy was proof against his death, which he forecast almost to the day. In happier times he would undoubtedly have attained high rank in the profession.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on June 27 the following medical degrees were conferred:

D.M.—C. Hollins, C. A. Hinds-Howell.
B.M., B.Ch.—J. R. Nassim (in absence).

UNIVERSITY OF BIRMINGHAM

At a Congregation on July 5 the following medical degrees were conferred:

M.D. (*ex-officio*).—S. Zuckerman, C.B., D.Sc., F.R.S.
M.D.—A. E. Chaplin, C. R. St. Johnston, Yvonne J. Williams.
M.B., Ch.B.—P. G. Bevan (distinction in medicine), *Jeannie E. Roulston, E. J. Allaway, Barbara M. Ansell (distinction in surgery), J. R. Baker, W. I. H. Bourne, J. Butler, P. Y. Carlyle, Pamela J. Chappell, Fay P. S. Cull, E. J. Li. Davies, S. P. Dawson, Rosemary Dearden, W. B. L. Downing, Jean M. MacN. Dunn, Margaret J. Dutton, Jeanette G. Eveson, Barbara M. Finch, Frances A. Fourcres, D. M. Garratt, Joan E. Garside, N. L. Gilburn, F. R. Goodwin, P. H. T. Hall, Nora K. S. Howkins, P. J. L. Hunter, G. A. Jeffery, Jose V. Keats, H. M. Kent, D. E. T. Laird, J. Lapper, Sylvia E. Leather, D. McL. Maxwell, Rosemary G. Milton, J. Moss, G. C. Richards, P. Rigby, J. M. D. Roberts, T. B. Stirling, J. E. Tremlett, G. M. Turner, Evelyn D. Watkins, F. E. Webb, K. M. Williams, J. T. H. Wise, C. Wood, Mary P. Woodhouse, †Constance M. A. Bachtin, †D. P. Fitzgerald, †G. A. Readett.

* With second-class honours. † In absentia.

The following scholarships, medals, and prizes have been awarded in the Faculty of Medicine.

Queen's Scholarship (third year) and Peter Thompson Prize in Anatomy (third year), J. A. Ireland. Queen's Scholarship (fifth year), W. H. McIlveen. Queen's Scholarship (final year), D. H. Barnbrook. Ingleby Scholarships, D. H. Barnbrook and J. C. Haworth. Arthur Foxwell Memorial Medal and Russell Memorial Prize, J. C. Haworth. Sampson Gamgee Memorial Medal and Priestley Smith Prize in Ophthalmology, J. K. Baird. Leith Newman Prizes in Pathology (fourth year): Medical, J. M. Bishop and G. T. S. Willets; Dental, J. A. C. Smith.

John Barritt Melson Memorial Gold Medal (third year), D. F. Cole. *Industrial Nursing Prize*, Charlotte M. R. Webster. *Alexander Youngson Prize*, P. Goodwin and Dyllys A. Owen (divided). *Lawrence Barnard Carlton Scholarship*, E. A. Marsland. *John Humphreys Memorial Prize*, D. S. Shovelton.

UNIVERSITY OF DURHAM

Luccock Medical Research Fellowships have been established by King's College, Newcastle-upon-Tyne, as a result of the bequest of the late Mr. J. W. Luccock, who left his money "to enable research to be made and carried on as to the component parts of the blood of human beings with the view and in the hope that such research investigation and inquiry will be of benefit to the human race and increase the knowledge of the medical and surgical profession as to all matters relating to the blood which may result in the alleviation of human suffering and probably the prolongation of life." Fellows are required to pursue full-time research in the University of Durham in an approved subject in the field of medicine (including dental surgery). Senior fellowships are of the minimum annual value of £600, and junior fellowships £300; supplementary grants in aid of the expenses of the research may be sanctioned by the Council. Regulations governing the award of these fellowships may be had from the Registrar of King's College, Newcastle.

UNIVERSITY OF GLASGOW

At a Ceremony of Graduation held on July 10 the following medical degrees were conferred:

M.D.—J. Reid (with honours), *Margaret D. Giles, D. M. Armstrong, J. Macrae.

M.B., Ch.B.—*G. C. Provan, *J. F. Patterson, *Elizabeth M. Dallow, *J. Guthrie, *D. W. Menzies, *J. B. Ritchie, *R. W. L. Heddle, *Susanne Rosenfeld, *W. D. H. Conacher, *H. Stern, G. Adam, L. R. C. Agnew, C. M. Ball, G. N. Beck, W. G. A. Begg, H. Benson, Ruth K. Bowden, Agnes C. L. Bowie, W. Brodie, R. C. Brown, I. A. Buchanan, J. Burgoyne, Janet G. McE. Burnett, J. H. Cameron, F. W. Campbell, G. S. Carrick, J. Carswell, L. Casey, Nulece Cassells, H. Clark, Ruth A. Cohen, D. F. Coulter, Mary G. Coyle, A. J. Crowe, Helen M. Cunningham, Agnes C. Davidson, A. Deuchars, W. W. Douglas, T. Dungavel, A. M. Ferrie, G. H. Field, R. B. Forbes, R. R. H. Ford, W. S. Foulds, K. H. Fraser, W. Garrett, J. B. Gibson, J. McC. Gilmour, Agnes M. Gordon, Elsie R. Gordon, Catriona M. Gourlay, E. G. Green, K. Greig, Anne McL. Haddow, S. Happel, I. Harper, Isabella P. Harvie, R. W. Henderson, R. B. Hendry, M. MacR. Herbert, P. A. Hood, J. R. S. Hutchison, R. McG. Inglis, J. G. Kennedy, J. S. P. Kerr, Ruth A. Keymer, Margaret G. Kirkwood, W. Lees, E. C. Levine, J. Levy, Janet J. Logan, T. Logan, C. P. Lowther, A. McClelland, Sarah C. McEwan, A. J. Maciver, S. McKechnie, W. J. M. Mackenzie, N. A. MacKillop, J. McG. McKinnon, J. Mackintosh, D. A. McLaren, G. K. McLellan, J. F. McMin, Anna S. MacTavish, A. S. MacVicar, J. S. Marshall, R. Martin, Dorothy J. Miller, J. R. Milne, Mary A. Mullen, I. B. Munro, J. McE. Neilson, A. Poli, J. A. E. Primrose, H. Revill, H. A. N. Richmond, J. L. Robertson, J. S. Scott, W. J. C. Scott, W. Seright, Margaret R. S. Smellie, Margaret A. E. Smith, Mary D. Smith, Marjory B. Snodgrass, J. T. T. Stark, Elizabeth T. Steel, I. F. Stewart, R. G. Stewart, J. Stoll, N. Watson, Anne B. Watt, J. White, Edith J. Whitelaw, L. Whyte, T. Wilson, B. A. Woodger, J. T. Young, T. G. S. Young.

The following prizes and medals were awarded:

Brunton Memorial Prize and Stockman Medal: G. C. Provan. *West of Scotland R.A.M.C. Memorial Prize and John W. Weir Prize*: Elizabeth M. Dallow. *McCawen Medal in Surgery*: R. W. L. Heddle.

* With commendation.

UNIVERSITY OF DUBLIN

The following medical degrees were conferred on July 3:

M.D.—C. W. Bradfield, D. P. Burkitt, R. H. Simon, R. T. Towson. M.B., B.Ch., B.A.O.—A. B. Boyle, R. P. Brown, T. T. Chapman, C. R. Crawford, D. F. Doherty, R. G. Emerson, P. B. B. Gatenby, Hilary Gruson, Jean F. W. Henry, J. Higginson, N. Jaswon, Ethel O. Johnston, Joan H. Kelly, W. R. Lamb, J. R. Lowe, J. B. H. Lusk, H. F. McElligott, F. H. Moore, F. P. Myles, O. M. O'Malley, R. D. H. Parker, R. M. Pritchard, I. Sevvitt, O. M. P. Tobias, Mona C. Warren, R. J. S. Weir, K. H. McK. Young.

QUEEN'S UNIVERSITY, BELFAST

The following candidates have been approved at the examinations indicated:

M.D.—J. H. Scott (with gold medal), *G. F. Adams, *W. H. Hood, *J. A. Smiley, T. J. M. Barber, T. H. D. Millar, J. M. Beare, A. M. Blackstock, A. A. H. Gailey, G. Gregg, R. A. Pypcr, R. H. F. Smith, E. C. Torrie.

M.B., B.Ch., B.A.O.—S. T. Armstrong, P. K. Boylan, E. J. H. Byrne, A. C. Darrab, C. De Lary, Christina M. Dornan, Irene M. Emerson, Mary F. Gregg, H. Hegon, T. D. Hurriott, A. L. Hyman, W. T. Joseph, Dorothea B. Keith, D. Kernohan, B. U. Killen, H. M. McClatchey, Dorothy McDowell, S. P. McGibbon, Doris A. McKinley, P. G. MacLarnon, B. Murray, J. Patterson, Vivien R. G. Poots, J. Rawe, J. E. Reid, W. B. Rodgers, K. Sax, W. J. W. Speedy, Vera A. Sullivan, C. A. K. Tully, Alice M. Williams, G. Wolfenden.

* With high commendation. † With commendation.

The Department of Health for Scotland announces that ex-Service men and women with first-class qualifications as nursing orderlies will have the chance of becoming State registered nurses after an intensive course of one year. Training for State registration normally takes three years. The General Nursing Council for Scotland, however, has agreed to allow ex-Service men and women to sit the examinations, after this intensive course, if they have had two years' experience of nursing in a Service hospital under State registered nurses, and have, while in the Services, qualified as nursing orderly Class I or nursing member Class I (Army); leading sick berth attendant (Navy); leading aircraftsman or aircraftswoman in the trade of nursing orderly (Air Force).

Medical Notes in Parliament

Free Choice

Mr. JOHN MCKAY on June 28 asked the Minister of Health to give an assurance that under the National Health Service Bill patients would have a free choice of doctors and not be restricted to the doctors covering the district in which the patients lived and who had made a contract of service under the National Health Service Act.

Mr. BEVAN said he could give this assurance. It was intended to give patients the widest possible choice among practitioners taking part in the new Health Services, but the details of the way in which this could be arranged must be a matter for regulations.

Medical Service for Coalminers

Mr. WILLIAM FOSTER, on July 2, invited Mr. Shinwell to make a statement of the progress made in the establishment of a medical service scheme at collieries in the mining industry.

The question was answered by Mr. GAITSKELL. He said arrangements for the erection of five experimental types of medical treatment centres were completed. It was hoped that all would be built and in operation by the end of the year. The construction of permanent centres, following experience with the experimental types, would take much longer. Meanwhile suitable first aid or other accommodation was being adapted at selected collieries for use as centres. The immediate aim was to have about fifty adapted centres in operation as soon as possible. Further progress would be made as labour and materials became available to make the necessary adaptations and the supply of nurses for this work increased.

New Rates of Pay for Medical Services

Mr. LAWSON announced on July 5 revised rates of pay for officers of the medical, dental, and veterinary services of the Armed Forces, and further made a statement on retired pay. Mr. Lawson said that as regards medical and dental officers the Government had decided that, from July 1, 1946, there would be a common scale of pay and time promotion in each of these two branches in all three Services. Officers would be appointed in the rank of acting surgeon lieutenant R.N., lieutenant, or flying officer, and promotion would be by time to surgeon lieutenant R.N., captain, or flight lieutenant after one year, and to surgeon lieutenant-commander, major, or squadron-leader after eight years. Thereafter promotion would be by election. Rates of pay would be as follows:

Approx. Age	Service	Rank	Pay (Daily)
25	On appointment ..	Acting Surgeon Lieutenant R.N., Lieutenant, or Flying Officer	s. d. 22 0
26	After 1 year's service	Surgeon Lieutenant R.N., Captain, or Flight Lieutenant	28 0
28	" 3 years "	"	31 0
30	" 5 " "	"	34 0
32	" 7 " "	"	37 0
33	" 8 " "	Surgeon Lieutenant-Commander, Major, or Squadron-Leader	43 0
35	" 10 " "	"	46 0
37	" 12 " "	"	49 0
39	" 14 " "	"	52 0
		Surgeon Commander, Lieutenant-Colonel, or Wing-Commander (on appointment)	58 0
		" after 2 years ..	61 0
		" " 4 " "	64 0
		" " 6 " "	67 0
		" " 8 " "	70 0
		Surgeon Captain R.N., Colonel, or Group-Captain (on appointment)	75 0
		" after 2 years ..	78 0
		" " 4 " "	81 0
		" " 6 " "	84 0
		Surgeon Captain R.N. (after 8 years as such), Brigadier, or Air-Commodore	87 0
		Surgeon Rear Admiral, Major-General, or Air Vice Marshal	110 0
		Surgeon Vice-Admiral, Lieutenant-General, or Air Marshal	135 0

Mr. Lawson also furnished a table giving the daily rates of pay for dental and for veterinary officers. He added that it was intended to continue the arrangement under which a medical or dental officer commissioned after holding an approved whole-time appointment in a recognized civilian hospital might be granted an ante-date of seniority. In future, however, there would be a common rule for all three Services and the ante-date, which would count towards the service qualifying for

increments of pay and for promotion to the rank of Major or equivalent in the other Services, would take effect on completion of 12 months' service. The arrangements for the encouragement and reward of specialization were still under consideration.

Turning to Service retired pay and gratuities, Mr. Lawson reported that the new general scheme of service retired pay and gratuities for Regular officers, details of which were given in Appendix III of the White Paper, Command 6750, would also apply to permanent Regular medical, dental, and veterinary officers who were serving on the active list on December 19, 1945, or who were commissioned after that date. There would be some adjustment on the lines of existing arrangements for Naval medical officers who retired with less than 25 years' service after having received the special gratuity of £1,000 which was payable under the old code. Medical, dental, and veterinary officers now serving with permanent Regular commissions would, like other officers, remain eligible, if to their advantage, for awards under the regulations now superseded, instead of the new terms. (See paragraph 67 of Cmd 6750.) Officers who retired with retired pay before December 19, 1945, and who served during the war, would be allowed reassessment of their retired pay in respect of their war service under the terms of the scheme announced in the House on April 15 by Mr. Lawson.

Birth Rate and Population Inquiry

Mr. CHRISTOPHER HOLLIS, on July 8, opened a discussion on the birth rate. He said Britain would have something like a stable population for some time but would, about the 1970's, be in danger of the beginning of a rapidly declining population. Some means should be discovered to prevent this decline. The number of children born depended on the extent to which people were able to have faith in the purpose of life. He pointed out that there had not been the decline in maternal mortality that there had been in every other mortality. One reason for this was the gradual raising of the age at which marriage took place and at which the first child was born. To decrease maternal mortality marriages should take place at an earlier age. That was an economic problem.

Mr. PAGET said the birth rate might have to be corrected by a policy of immigration.

Replying for the Ministry of Health, Mr. KEY said a commission was inquiring into the question of population. Last year they took a family census from which the Government might be able to discover whether the size of families was declining and if childlessness was increasing. There was at the moment a considerable increase in the birth rate and figures seemed to indicate that the size of the family was increasing, but until the Government had a full report from the commission it would not be in a position to analyse the problem nor to know its real causes and its extent. He could not indicate when the commission would finish taking evidence, nor when it was likely to produce its report.

Penicillin Supplies

Mr. WILMOT said on July 8 that supplies of penicillin were steadily increasing, but it would not be possible for some time accurately to estimate the demand. He would consider discontinuing control measures immediately it became apparent that supplies were adequate to meet an uncontrolled demand. At present control was made more effective by taking proceedings against the person who, without approved prescription or authority, tried to buy penicillin, as well as against the supplier.

Oversea Service of Specialist M.O.s

Mr. BOWDEN reported on July 9 that specialist medical officers recently called to the Army were being sent home for six to eight weeks to await posting abroad. Mr. LAWSON explained that drafts of specialist medical officers were normally despatched at monthly intervals, the date of each draft being adjusted to ensure that all the officers comprising it received fourteen days' embarkation leave after their primary training. Occasionally the despatch of officers was delayed because of shipping difficulties or late notice of alterations in overseas requirements. Such cases were exceptional and did not materially affect the position of officers now over-seas who awaited release. In certain theatres and for certain special subjects the release of these officers had been retarded, but this was primarily due to the difficulty of obtaining replacements from the civilian profession.

Bread Rationing Scheme

Mr. STRACHEY announced on July 10 that all hospital nurses qualify for the ration of 11 oz. of bread a day and that hospitals would obtain this allowance for those nurses who were resident. Young manual workers between the ages of 11 and 18 would

be rationed both as adolescents and as manual workers and would receive 18 oz. a day, or 14 in the case of girls. He added that this was right, as their psychological and physiological needs for food were especially large. Mr. Strachey estimated the classes of consumers under the bread rationing scheme to be: children under 1, 800,000; children 1-5, 3,000,000; children 5-11, 3,400,000; adolescents 11-18, 5,300,000; normal adults, 22,000,000; expectant mothers, 600,000; manual workers (women), 3,000,000; manual workers (men), 9,000,000.

Notes in Brief

British Guiana maintains seven public hospitals containing in all over 2,000 beds; and Mr. George Hall is satisfied that these arrangements meet the needs of the community. Substantial reconstruction is desirable, and the Government of British Guiana is considering what improvements are possible within the limits set by its financial resources.

Mr. Strachey is anxious that everything possible shall be done to encourage the development of products which can be used to replace soap. Over a thousand firms have already been licensed to produce or market soap substitutes.

Medical News

A meeting of the Middlesex County Medical Society will be held at North Middlesex County Hospital, Silver Street, Edmonton, N., to-day (Saturday, July 20), at 3 p.m.

A Japanese Prison Camp Art Show has been arranged at the Alpine Club, 74, South Audley Street, London, W. It is open daily until July 27, 10 a.m. to 6 p.m. except Sunday. There is an exhibition of drawings and paintings in Chinese mediums by Dr. R. Kenneth McAll, internment camp medical officer 1942-5.

The 150th anniversary of the opening of the Royal Sea-Bathing Hospital, Margate, will be commemorated on the afternoon of July 23 at the hospital, Canterbury Road, Margate. The president, the Earl of Athlone, and H.R.H. Princess Alice, Countess of Athlone, will attend the ceremony.

In connexion with the Davidson Clinic, Edinburgh, a summer school will be held from July 31 to August 6. The main theme will be "Family Relationship." The opening address will be given by Dr. Scott Williamson of the Pioneer Health Centre, Peckham. A series of addresses will be given by Dr. E. A. Bennet of the West End Hospital for Nervous Diseases, London, and discussion groups will be led by members of the Davidson Clinic staff. Further information can be obtained from the secretary, 26, Chalmers Street, Edinburgh.

On July 4 the American Ambassador, Mr. Averell Harriman, unveiled a tablet in the Middlesex Hospital to commemorate a gift of £25,000 to the hospital from the surplus funds of the American Ambulance in Great Britain.

The following members of the medical profession were called to the Bar on July 3: J. Tarsh, M.B., Ch.B., and Squadron Leader F. E. Fletcher, M.B., Ch.B. (Lincoln's Inn); R. C. Burton, M.B., Ch.B. (Middle Temple); and S. C. Gawne, M.D. (Gray's Inn).

Sir Stewart Duke-Elder, ophthalmic surgeon to St. George's Hospital, has been elected an honorary Fellow of the American Medical Association.

The Ministry of Health announces that consequent on the decision to place penicillin on sale through the normal trade channels, the free supply to local authorities of penicillin, including penicillin in oil-wax suspension, for the treatment of venereal diseases will be discontinued; and it will now be necessary for local authorities to place orders for future supplies at trade rates with manufacturers authorized to supply in accordance with the formulae of the *British Pharmacopoeia*.

From June 20 the statutory controls regulating the distribution of nurses (male and female) and midwives ceased to operate. It is no longer necessary for employing authorities to consult the Ministry of Labour and National Service before engaging staff for nursing or midwifery or obtaining recruits to train in these professions. Similarly nurses and midwives or persons seeking to train as such are free to take up appointments or training otherwise than through the nursing appointments offices. In addition, State registered nurses and fully trained midwives will not in future be required on becoming qualified to give a year's special service. In consequence of these changes in the situation, the co-operation of employing authorities in notifying the termination of employment of nurses and midwives is no longer necessary. Restrictions on the engagement of male radiographers and physiotherapists in the age group 18-30 inclusive also come to an end. The removal of these controls does not mean that all persons in the classes specified above are necessarily free to leave their present employment.

After consultation with hospital, nursing, and other interests in Scotland, the Nuffield Provincial Hospitals Trust has undertaken to accept financial responsibility for the establishment in Scotland of a nursing recruitment service similar to that which has operated in England for the past six years under the auspices of King Edward's Hospital Fund for London and the Nuffield Trust. The service will operate by means of nursing recruitment centres in charge of qualified and experienced staff. Lord Nuffield's trustees have appointed a Scottish Nursing Recruitment Committee responsible for the direction of the work, and the members include Sir Robert Nimmo (chairman), Dr. A. Greig Anderson (vice-chairman); Dr. W. L. Burgess; and Prof. Thomas Ferguson.

MACKENZIE INDUSTRIAL HEALTH LECTURE

Dr. Donald Hunter, F.R.C.P., will deliver the Mackenzie Industrial Health Lecture at B.M.A. House on Wednesday, July 24, at 5.45 p.m. The title of the lecture is "Academic Aspects of Industrial Medicine," and admission is by ticket only. The lecture will be confined to persons, lay and medical, who are professionally interested in industrial medicine. Tickets of admission can be obtained from the Secretary, B.M.A. House, Tavistock Square, W.C.1, and early application is requested as the number is limited.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* there was a large fall in the notifications of measles 339, while an increased prevalence was recorded for scarlet fever 122, whooping-cough 47, diphtheria 39, and dysentery 30.

Notable decreases in measles were London 111; Lancashire 47, Cheshire 42. The decline in scarlet fever was fairly general throughout the northern section of the country, but in the southern section a slight rise occurred.

The only large variation in the local trends of whooping-cough was an increase in Essex of 52. The largest fluctuations in diphtheria were an increase of 21 in Lancashire and a fall of 14 in Yorkshire West Riding. Notifications of dysentery were largest in Lancashire 49, London 15, and Warwickshire 10.

In *Scotland* there were decreases in the incidence of diphtheria 24, measles 53, and whooping-cough 25. The largest local fall in diphtheria was Glasgow 14.

In *Eire* the notifications of infectious diseases varied only slightly from the level of the preceding week. Although diarrhoea and enteritis fell by 3 for the whole country, a rise of 10 was recorded in Dublin C.B.

In *Northern Ireland* the only feature of note in the returns was an outbreak of measles involving 16 cases in Ballycastle R.D.

Infectious Diseases During the Second Quarter

Notifications generally during the June quarter of this year have been below the average of recent years.

Notifications in Second Quarter

	1942	1943	1944	1945	1946
Scarlet fever	14,592	23,785	21,692	17,139	13,958
Whooping-cough	18,291	27,297	30,347	13,907	25,559
Diphtheria	8,911	8,355	6,973	5,971	4,662
Measles	73,962	127,131	32,344	165,388	42,166
Cerebrospinal fever	1,859	916	873	723	756
Dysentery	1,726	1,683	2,835	5,325	2,259
Paratyphoid and typhoid	207	183	136	119	112

Diphtheria notifications have fallen steadily and are now only slightly over half the total of five years ago. The 4,662 cases in the second quarter of this year give the lowest number recorded in any quarter. The totals for scarlet fever and enteric (typhoid and paratyphoid) are the lowest for the second quarter in recent years.

War Losses

War losses amounted to 400,000 persons for the United Kingdom according to the *League of Nations Monthly Bulletin of Statistics*, No. 5. This figure included: military losses of 245,000 killed and 53,000 missing; 30,200 merchant seamen killed and 5,260 missing. Nearly 60,600 civilians were killed in the United Kingdom, of whom 7,700 were children under 16.

Week Ending July 6

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 997, whooping-cough 2,247, diphtheria 290, measles 4,524, acute pneumonia 478, cerebrospinal fever 37, dysentery 87, paratyphoid 10, typhoid 13.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 29.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1946					1945 (Corresponding Week)

ANY QUESTIONS?

Contact Dermatitis in Apiarists

Q.—*An apiarist changed the crates in the hives, and that evening his penis became itchy and swollen. Two days later the penis was lightly erythematous with bullous oedema at the tip. The only other lesions were slight swelling of both upper eyelids and minute itchy macules on the front of both wrists and elbows. The oedema subsided and the macules faded, with subsequent fine desquamation, after appropriate treatment. Two identical attacks occurred in May and September last year, and between these attacks he had actually handled bees on several occasions without mishap. What is the explanation of this?*

A.—The description given is almost certainly that of a contact dermatitis. The parts which have been in contact with the excitant become very itching or burning and develop an erythematous, papulo-vesicular, vesicular, or pustular rash, depending on the degree of reaction. This is followed by the formation of crusts or scales. The eruption may be accompanied by swelling of the face, particularly the eyelids. The part of the penis affected would be in agreement with this hypothesis, the excitant being conveyed by the hands. Many apiarists when handling crates cover them with a cloth rinsed in lysol—a common cause of contact dermatitis. If this is not the case with your apiarist other excitants must be looked for and patch tests may be necessary to trace the cause (*Clinical Allergy*, L. Tuft). The treatment is complete avoidance of the cause.

Gastric Aspiration

Q.—*What are the indications for gastric aspiration? How is it performed?*

A.—Intermittent gastric aspiration is an invaluable adjuvant to treatment in pyloric stenosis. With it some cases will settle down completely, and all patients should have the gastric contents aspirated daily and the stomach washed out with normal saline solution for at least a week prior to operation. It should also be employed before Rammstedt's operation for congenital pyloric stenosis in infants as well as in certain types of poisoning. A large stomach-tube, about 1 cm. in diameter, should be used. It should be connected to a funnel by means of a glass connexion and a piece of rubber tubing. The funnel is filled with normal saline solution, and before this has run through the funnel is inverted so that the gastric contents will be siphoned off. This manœuvre should be repeated until the washings are returned clear.

Continuous gastric aspiration is of great value in high intestinal obstruction, after operations on the gastro-intestinal tract, and in all post-operative conditions characterized by vomiting. For this purpose a Ryle's tube is most convenient as it can be passed through the nose and retained in position for several days. Continuous suction is provided by means of an inverted Winchester bottle, which is hung above the patient's head from some convenient stand or bracket by the bedside. It is fitted with a rubber bung through which pass two pieces of glass tubing, one reaching to the bottom and the other going just through the bung. The bottle is filled with water and the Ryle's tube is connected to the longer of the two glass tubes; the shorter tube leads by a piece of rubber tubing to a bucket on the floor. The rate at which the water runs out and at which the gastric contents are aspirated is regulated by means of a

screw-clip on the rubber tubing. The quantity of gastric contents removed must be measured, for the patient should not be allowed to become dehydrated; rectal or intravenous saline infusions may be necessary to combat this.

Yeast and Baldness

Q.—*A newspaper reports that in America yeast grows hair on the scalp of even old men. Is that so?*

A.—The newspaper report must have grossly distorted the facts. Greying of the fur occurs in rats kept on artificial diets lacking pantothenic acid and para-aminobenzoic acid, both of which are members of the vitamin B complex and occur in yeast. There is no evidence, however, that either of these substances can cure greyness in human beings. They have both been submitted to clinical trial in America, and the results have been entirely negative. No harmful effects are produced by taking yeast over a long period, although in some people it may cause intestinal flatulence and diarrhoea. It can be taken in the form of yeast tablets, dried yeast powder, or in the form of fresh yeast. There are no reports on the application of yeast to the scalp.

Diphtheria Immunization

Q.—*A.P.T. often causes a reaction in older children. Should one use T.A.F. when doing refresher immunization against diphtheria?*

A.—The refresher or boosting dose of diphtheria prophylactic should, if the child has received a primary immunizing course at one year of age, be given at the time of school entry. While reactions have occurred at this age they are not as a rule serious and do not preclude the use of A.P.T., the best immunizing reagent, for stimulating a waning immunity in young children. If, however, a primary course has been given at, say, four to five years, and it is desired to give a boosting dose five years later, A.P.T. may cause a severe reaction, and it is in this age group that the use of T.A.F. is particularly recommended. Alternatively, the children may be Schick-tested before the proposed boosting dose, and only those showing straight positive reactions should be given a further dose of either A.P.T. or T.A.F. It does not matter whether A.P.T. or T.A.F. has been used for the primary course, and only a small dose of prophylactic (0.2 ml. A.P.T. or 0.5 ml. T.A.F.) is needed as a booster dose to produce the necessary response.

Toxicity of Ketene

Q.—*Can you give me any information about the toxicity of ketene, CH₃CO? What concentration is considered dangerous, and what are its effects?*

A.—Ketene is a colourless gas with a peculiar penetrating smell resembling chlorine and acetic anhydride. It readily polymerizes on standing, and on strong heating decomposes into ethylene and carbon monoxide. Its spontaneous condensation is accompanied by considerable evolution of heat; there may be a fire hazard involved in the handling of it. The literature indicates that ketene is poisonous and irritant, though its precise action on the human body has not been described. It seems to attack mucous membranes, and Staudinger and Klever say that it "produces, even by inhaling small amounts, severe headache." The safest way to handle ketene would be by processing in an enclosed system, so that no one is exposed to its irritant properties.

Travel Sickness

Q.—*What is the best treatment for travel sickness—during the journey and on arrival? Is there any special treatment for air-sickness?*

A.—Experiments done with commando troops during the war showed that the only drug which significantly affected the incidence of sea-sickness was hyoscine; 1/100 gr. (0.65 mg.) may be taken orally before going aboard and repeated if necessary during the journey. There is no need to give any treatment on arrival at the destination, when recovery takes place rapidly. This treatment, which may be used for sea-sickness, air-sickness, or car-sickness, is not invariably successful, but it appears to be the best at present available. It must be borne in mind that in a high proportion of cases the sickness is psycho-

logical in origin. Such cases respond to almost any treatment prescribed with sufficient confidence. Many proprietary remedies owe their apparent efficacy to this fact.

Cause of Psoriasis

Q.—Is the causative agent of psoriasis carried in the blood stream? What is the latest treatment for it?

A.—There is no known single causative agent for psoriasis. It is probably different in different individuals and for different attacks, and it may upon occasion be carried in the blood stream—e.g., the toxins from a streptococcal throat may provoke an attack of psoriasis. Treatment is clearly an individual problem for every case, or indeed for every attack of psoriasis. As to the general lines of treatment, the reader should consult a textbook on dermatology or recent papers, e.g., *Encyclopaedia of Medical Practice* (Butterworth).

Dermatitis due to Nail Varnish

Q.—A mother, aged 59, and her daughter, aged 26, both complain of brittle and splitting finger-nails and an intensely irritating rash on the face. This is usually on the chin and round the mouth, is much drier than the surrounding skin, and peels readily. The nails split into two layers, the top layer becoming torn off in a ragged fashion. Both women are housewives and have their hands often immersed in water, and they use nail varnish. Can you suggest an explanation?

A.—Two possible explanations are worth consideration. These patients may be suffering from a dermatitis due to nail varnish. This may lead to deterioration of the nails and, without causing dermatitis of the finger ends, may give rise to a very puzzling irritable dermatitis of the face due to the finger-nails touching the face. The patients should be patch-tested for sensitiveness to the varnish by applying a little to the upper arm and observing whether it produces any rash in this site. Treatment would be by abandoning nail varnish.

Another possible cause is general constitutional and nervous debility giving rise to dystrophy of nails and an eczematous eruption of seborrhoeic type on the face. This would call for general medical investigation, especially of the nutritional, endocrine, and nervous side of the problem, and would need treatment along appropriate lines. (See *Journal*, 1941, 2, 855.)

INCOME TAX

Expenses Incurred while not actually in Practice

"RELEASED," while on service abroad, sold his practice as from January 1, 1946, to his locum tenent. He returned to this country on April 12, 1946, and is acquiring a house and a practice elsewhere as from August 16. He has recently had his car overhauled at a cost of £130. Can he obtain income tax relief on this, either (a) by deducting that amount as an expense or (b) by adding it to the written down value of his car?

** As the "wear and tear occurred while the car was used in the practice" it seems equitable that an income tax allowance should be made for the expense, but we are not aware of any provisions of the Income Tax Acts under which such an expense can be deducted if it was incurred when the source of income was not then existing. Additions to written down value are restricted to expenditure on improvements, or additions, and a claim under alternative (b) is likely to be refused—but it is the better chance of the two. It follows that further expenses—e.g., on books, instruments, etc., had better be deferred until after August 16.

Payment of Tax under a Misapprehension

J. L. joined the Forces in August, 1942, and his employers agreed to make up his pay to the civilian level. His pay rose above that level, and he notified his employers accordingly; but for a considerable time they continued to make payments to his account and to deduct tax therefrom. The question of refunding to the employers is now being dealt with; J. L. has refunded the net amounts paid to him and asks whether the amount representing the tax should not be refunded by the Inland Revenue—who have declined to do so.

** The tax having been deducted and handed over to the collector, it is J. L. who suffered the tax and is entitled to reclaim it. It is true that the payments from which tax was deducted have proved not to be J. L.'s income at all, but that does not seem to alter the fact that it was J. L. who was regarded as in receipt of the income, and he must be held to have suffered the tax, and therefore to be entitled to any refund that may be due on the facts as they are now established.

LETTERS, NOTES, ETC.

Medical Educational Films

Dr. R. C. MACKETH, Chairman of the Medical Committee of the Scientific Film Association, writes: Prof. Niels Dungal's survey (June 15, p. 923) is most useful. He has evidently been in close contact with U.S.A. than this country, but much work has been done here to meet the difficulties he notes. The Royal Society of Medicine financed a joint work by the R.S.M. and the S.F.A., and 800 medical films have been viewed. Catalogues will be published (one is now at the printers) giving the information collected. The S.F.A. agree strongly with Prof. Dungal that it is desirable to be able to obtain an "adequate judgement whether a likely-looking film is really suitable for the purpose desired." Such judgements are provided by the S.F.A. Appraisal Scheme. The S.F.A. Medical Committee are shortly publishing a catalogue of films on anaesthetics which will include content, appraisal, and distributors of each film. As regards "The Need for Organization" the following items will be of interest. 1. Suggestions have been collected from deans of medical schools as to subjects on which they would welcome medical teaching films. These suggestions are available to would-be sponsors of films. A scheme for voluntary co-ordination of production of medical films is in operation and was noted in the *Journal* of May 18 (p. 779). 2. We have been able to promote the printing and circulation of copies of a number of medical films and, pending the setting up of an active central medical film library, we have accepted copies of films. The international exchange of educational films is likely to be taken up actively by Unesco in the not very distant future. 3. In conjunction with the Royal Society of Medicine a very successful meeting was held in February, 1946, to discuss "The Place of the Film in Medical Education." The papers and discussion are being printed as a pamphlet.

Ministrations of the Clergy on Patients in Hospital

In the spring of 1945 a body of laymen, with the expert assistance of two doctors, a clergyman, and a nurse, sent out a questionnaire to all medical superintendents of hospitals in Denmark and to the clergymen and nurses attached to these hospitals. The object of this poll was to ascertain the attitude of Danish medical superintendents of hospitals to the spiritual welfare of their patients. Altogether 118 superintendents answered the numerous questions set them, and after the omission of eight answers not found appropriate, there remained 110 which are discussed very fully by Dr. Karl Söndergaard in the journal of the Danish Medical Association, *Ugeskrift for Læger*, for June 13, 1945. A classification of the ages of the medical superintendents failed to show any age difference in their attitude to this problem, presumably because, as Dr. Söndergaard suggests, a man's theological outlook has usually crystallized out for good by the age of 30. But the poll showed that the doctors in charge of patients suffering from chronic diseases were as a class much more interested in the spiritual welfare of their patients than the doctors in charge of hospitals with a rapid circulation of patients. While many medical superintendents gave the clergy attached to their hospitals every facility for getting into touch with their patients, imparting details concerning their health to help the clergy in their appreciation of the situation, other medical superintendents declared that they did not co-operate at all with the clergy, of whom one wrote that they have "neither the right to receive information nor the qualifications to understand morbid conditions." But while some invoked professional secrecy as a reason for passive obstruction, others found they could speak freely with a hospital clergyman who is also bound by professional secrecy and "has just as much right to have access to case records as an ordinary probationer nurse." Dr. Söndergaard finds that the medical superintendents of hospitals were as a class, and with the exception of medical psychiatrists, less familiar with modern psychiatry than the clergy. As was to be expected, the clergy attached to hospitals in the charge of medical superintendents "who cared for none of these things" often found their work disheartening. The most perplexing question, and one which several Danish superintendents declared they did not understand was: "In what do you see the difference between, or the similarity of, psychotherapy and Christian spiritual care?" To which one of the superintendents replied that the difference lay in the object sought, psychotherapy aiming at healing a morbid mental process, Christian spiritual care aiming at helping the patient in his religious life and acting in certain cases as effective psychotherapy.

Treatment of Sterility in Women

Dr. J. B. PRIMMER (Dunfermline) writes: We might do worse than return to some of the older methods. In my early days, before National Health Insurance had been thought of except in Germany, with more time available I used to treat sterility in the patient's home by means of dilatation of the cervix with Hegar's dilators, a method referred to by Dr. D. Currie (June 29, p. 997). The results were good in cases of from two to four years' sterility. If vaginismus was the cause, the wearing of a glass dilator with supports proved effective, though my experience of this was limited.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 20 1946

NATIONAL HEALTH SERVICE BILL

ANALYSIS OF RESULTS OF COMMITTEE STAGE OF PROCEEDINGS

The Committee Stage of the National Health Service Bill was completed on July 3. Below is an analysis of the results of the proceedings, which lasted twenty days. Under each Clause in the Bill, proposed new Clauses, and the various schedules, extracts are given from the Official Report. These are shown under three headings: "Change" means that an amendment was agreed to; "Promise" indicates a Government promise; and "Intention" a Government intention. In each case the section and subsection of the Clause are recorded, and the final reference is to the column number in Hansard. It is expected that the Report Stage of the Bill will be taken on July 22 and 23 and the Final Reading on July 25.

Central Administration

Making of Regulations (Clause 1)

Intention.—Mr. BEVAN: "Any regulation dealing with general health service matters will obviously be agreed with the Minister beforehand, but he would not put every regulation before such body; otherwise it would be hopelessly overburdened." (Col. 17.)

[His example of a regulation which he would not put before a highly specialized medical body" was one relating to superannuation.]

Members of Council in Relation to Advisory Committees (Clause 2 (1))

Promise.—If, on further examination of Clause 2 (3), it is shown that the wording prevents the Council from advising the Minister on the advice given to it by one of the standing advisory committees, the Minister will alter the wording on the Report stage. (Col. 31.)

Mr. BEVAN: "We were very anxious that the Central Council should have the opportunity of reviewing for the Minister the advice of a standing advisory committee in the light of its effect on the general medical services. That is the reason we secure in this Subsection that the advice of the standing advisory committee goes simultaneously to the Minister and to the Central Council. . . . We do not want a Central Council that is a specialist body. . . . We want to have the Central Council not limited in any inappropriate way, but limited to giving general advice."

Variation of Constitution (Clause 2 (2))

Promise.—The Minister will introduce an amendment on the Report stage to make any alteration of the constitution of the Central Council subject to a negative Resolution of the House, not a positive Resolution. . . . If it were made subject to a Prayer, all the protection necessary would be given. (Col. 38.)

Mr. BEVAN: "If the body were so reorganized as to disturb the balance which already existed, the defenders of the existing balance would almost certainly put down, or inspire, a Prayer against the Regulation. I hope I shall not be pressed to go beyond that, because this is a matter which is not of such weight as to warrant a positive Resolution."

Standing Advisory Committees (Clause 2 (3))

Intention.—On the question of naming them in the Bill Mr. BEVAN said: "I thought the best possible thing to do would be to set up such standing advisory committees as the Central Council itself advised the Minister were necessary, and add to them from time to time, or take away from them as the exigencies of practical realities dictate." (Col. 42.)

Standing Advisory Committees (Clause 2 (3))

Intention.—Mr. BEVAN: "The Central Council itself will always have representatives on each of the standing committees, and, of course, the standing committees are set up after consultation with the Council. There is no danger of any divergent lines of activities. I can also give the assurance that although in urgent circumstances it may be necessary for the Minister to act on the advice of a standing committee, nevertheless, that report will be made known to the Central Council and, in fact, will form part of the Central Council's annual report. I think there is no difficulty at all about this." (Col. 48.)

Publication of Report (Clause 2 (4))

Change.—Words "after consultation with the Central Council" inserted in connexion with suppression of any part of the report as contrary to the public interest.

Mr. BEVAN: "It would seem to me an astonishing abuse of Ministerial power if the Minister proposed to suppress a portion of a report of a body of this sort without first of all telling the body about it. I think that would be perfectly reasonable and would be the normal practice, but if assurances are necessary I am perfectly prepared to accept the Amendment." (Col. 58.)

Powers of Standing Advisory Committees (Clause 2 (3))

Promise.—Mr. BEVAN: "I will look at it, and if it is necessary to do so we will make it quite clear that the standing committee will have power of initiation." (Col. 60.)

Integration of Services—Industrial Health Service (Clause 1 (2))

Intention.—On the question of the limitation of the sphere of advice that the Central Council might give, Mr. BEVAN said: "Where it might be limited, and I think properly limited, is in connexion with industrial health services. The Central Council might feel there ought to be an industrial health service. We all think there ought to be an industrial health service included in the wider scheme, and such a scheme will be, I hope, very shortly included in the scheme. The only reason why it is not there now is because it was administratively indigestible to take all those services into the present scheme. . . . We ought to see what sort of pattern emerges from this before embracing an industrial health service." (Col. 61.)

Sphere of Central Council (Clause 1 (2))

Promise.—On the objection that the Bill as drafted confined the advice of the Central Council to services that were already provided and not on services that were not, but should be, provided, Mr. BEVAN said: "If there is limitation we will remove it, though I doubt very much whether there is." (Col. 62.)

Hospital and Specialist Services*Ambulance Services (Clause 3 (1) (b))*

Intention.—Mr. KEY: "Services required at or for the purposes of hospitals include the provision of transport of all kinds, including the necessary ambulance transport for the hospitals concerned." (Col. 95.)

Definition of Specialist (Clause 3 (1) (c))

Intention.—Mr. KEY: "In the Bill there is no definition of 'specialist.' Since there is no definition, it will be left to the regulations which will be made under Clause 62 for the purpose for deciding the qualifications of the people who are to serve in that capacity. . . . The absence of a definition of 'specialist' gives us, when we come to the regulations, the necessary power of including in that service those people whose services will be essential at any particular time in the carrying out of this scheme." (Col. 98.)

Regional Boards (Clause 3 (1) (c))

Intention.—In reply to a request for an assurance that regional machinery would be set up, Mr. BEVAN said: "I am most happy to do so. The first thing I propose to do, immediately Parliament gives me authority, is to have the Regional Boards appointed. The second thing I propose to do is to ask them at once to prepare draft plans." (Col. 120.)

Appliances (Clause 3 (2))

Change.—The word "medical" has been deleted before "appliances" in two places in order to remove any limitation. (Col. 122.)

Expenses of Patients (Clause 3 (3))

Change.—The words "or to be incurred" have been inserted to ensure that in cases where it is necessary expenses may be paid before they are incurred. (Col. 123.)

Definition of Specialist (Clause 3 (1) (c))

Intention.—In connexion with the possible recognition of general practitioners as specialists Mr. BEVAN said: "I am proposing to ask the appropriate body—I would have to ask the Central Advisory Medical Committee first, because the Central Council will not be established for some time, and I may have to get this thing done rather hurriedly—and I will consult the profession as to what body they consider ought to advise me, on the definition of a specialist for the purposes of this scheme." (Col. 133.)

Access of General Practitioners to Hospitals (Clause 5 (2))

Promise.—Mr. BEVAN: "I am prepared to make a concession in the case of general-practitioner hospitals. There are instances all over the country where a person who is chronically ill goes into hospital because he or she cannot get treatment at home. It may be that they suffer from something which does not require specialist treatment but treatment by a general practitioner. I want to make it clear that the general practitioner should give that kind of treatment in a general-practitioner hospital. I propose to consider whether it is necessary to put down an Amendment to make that clear."

This statement referred to the private patients of general practitioners, and the Minister was then asked whether "the general practitioner was covered who was outside the service altogether, if there are such people." He replied: "Now the hon. Member is not pushing the door open, but is pushing the house down. If he is asking that a general practitioner who is entirely outside the public service is to have available the hospitals of the public service, he is asking for more than the specialist gets. . . . All I say is that if a doctor or a specialist cares to stay outside the service it will be a little hard for us to provide facilities. There must be some reason about this. I do not want to have a principle inserted in my scheme whereby general practitioners and specialists can sabotage the service by remaining outside. . . . I have said that I was prepared to consider putting down an Amendment to make it quite clear that the general practitioner in a general-practitioner hospital should charge for private patients and attend private

patients there, but I warn hon. Members that if they push this too far in another direction I shall have to resist with the utmost vigour." (Cols. 174-5.)

Future of Specialist Services (Clause 5 (2))

Intention.—Mr. BEVAN: "I want the specialist to spend as much time in the hospital precincts as possible. Indeed, I am hoping that, by enabling him to use the hospital facilities more and more, we shall slowly assimilate him into the hospital services, and that his desire to pursue private economic adventure outside will be lessened by it." (Col. 176.)

Specialists' Private Fees (Clause 5 (2))

Intention.—Referring to the specialist who would send his patient to a private nursing home in order to obtain higher fees Mr. BEVAN said: "The sooner that kind of specialist gets out of the hospital the better for the hospital service. That is a case of commercial-mindedness which would poison him and his associates. There must be a reasonable limit somewhere, and I think that the ceilings will probably be fixed fairly high, as they are now in many of these hospitals, and very good incomes—if I may change the phrase—would be obtained under them." (Cols. 190-1.)

Independent Specialist Opinions (Clause 5 (2))

Intention.—Mr. BEVAN reiterated that he could do nothing that would provide an inducement to practitioners to stay outside the scheme, and said that there should be no difficulty in obtaining independent second opinions. "Doctors will not be employees of the State." (Col. 195.)

Asked whether specialists could keep a substantial part of their time for private practice, Mr. BEVAN said: "This is a field in which the utmost flexibility will have to prevail. As long as a specialist is in the public service, as long as he is attached, no matter in how small a degree, he is conceived to be in the public service. In other words, there will be no question that he must spend 50% of his time in the hospitals and 50% elsewhere; it might be much smaller than that. As long as he is within the public service he will be covered." (Col. 197.)

Transfer of Hospitals to the Minister (Clause 6 (1))

Change.—Words "or attaching to" inserted to make clear that rights attaching to hospitals and the premises of hospitals are transferred with the premises themselves. (Col. 209.)

Change.—The following has been inserted: "rights and liabilities to which any such governing body or trustees were entitled or subject immediately before the appointed day, being rights and liabilities acquired or incurred solely for the purposes of managing any such premises or property as aforesaid or otherwise carrying on the business of the hospital or any part thereof, but not including any endowment within the meaning of the next following section or any rights or liabilities transferred under that section."

The purpose of the amendment is to make clear that the Minister will take over the contractual rights, etc., in connexion with the running of the hospital as well as the liabilities. (Col. 223.)

This does not apply to endowments. (Col. 225.)

Definition of Hospital in Certain Cases (Clause 6 (1))

Intention.—On the question of certain institutions, which may or may not be hospitals, Mr. BEVAN said: "The term 'hospital' of course, is defined, but the question what kind of institutions are taken over will depend very largely upon the recommendation of the Regional Boards and the ultimate hospital plan, and it would be difficult for me at this stage to say what the answer will be. However, it is not intended to take over institutions which are not specifically hospitals or ancillary to hospitals." (Col. 230.)

Use of Hospital Property (Clause 6 (4))

Intention.—Objecting to an amendment restricting the use of property to the purpose for which it was used immediately before the appointed day, Mr. KEY said: "We must be given

edom for reorganization and adaptability on the understanding, and the complete undertaking, too, that, as far as practicable, the purposes for which the foundation was made originally shall be observed in the scheme that is to be developed." (Col. 248.)

Transfer of Rights and Liabilities of Hospitals to the Minister (Clause 6 (6))

Change.—The following words have been inserted: "or to rights and liabilities arising under any enactment, scheme, or contract providing for the payment of superannuation benefits, except superannuation benefits payable in respect of officers employed for the purposes of a voluntary hospital who have ceased to be so employed before the appointed day, but this subsection shall be without prejudice to the provisions of Part I of the Act, relating to the transfer and compensation of officers and the superannuation of officers."

The purpose is to exclude from the transfer of rights and liabilities the rights and liabilities relating to superannuation in order that they may be considered with Clauses 63 and 72. But where a voluntary hospital has a liability for the payment of superannuation to somebody who has actually retired, the ability for that is transferred to the Minister. (Col. 252.)

Date of Operation of Scheme (Clause 6)

Intention.—Referring to the notification to voluntary hospitals about their position under the Act Mr. BEVAN said: "As soon as the Bill is passed we will, as I said the other day, establish the Regional Boards in order that the plans may be made as soon as possible, and, as they are being made, the hospitals will learn what their position is to be. Therefore it will not be 1948 before they will have an idea; it will be quite a substantial time before that, as the schemes themselves are being formulated. . . . The Bill gives the Minister power to bring parts of the scheme into operation at different appointed days, so that all the scheme will not be suspended until one appointed day in 1948. Some portions of the scheme will be coming into operation in the meantime. That itself will assist in limiting the period of apprehension." (Col. 262.)

Endowments of Voluntary Hospitals (Clause 7)

Intention.—In refusing an amendment transferring the hospital endowments to the management committee Mr. BEVAN said: "The management committee in the future, in rural areas, may spread over quite a distance in order to accomplish a 1,000-bed unit, so that in that circumstance it will be as remote an entity as the Regional Board. I cannot see that we are doing something sacrilegious in taking the money into a national pool and re-allocating it fairly, and that something much more humanitarian, more imaginative, and more sympathetic would be done by giving it to a management committee that does not exist at all at the moment."

He explained that "fairly" meant "in accordance with the number of beds and the requirements of the area." (Col. 272.)

Endowments of Voluntary Hospitals (Clause 7(2))

Change.—Words "such purposes relating to hospital services or to the functions of the Board under this part of this Act with respect to research as the Board think fit" inserted to make clear for what purposes the endowments left to teaching hospitals can be used. (Col. 281.)

Intention.—Mr. KEY: "The Regional Boards and management committees are to submit annual estimates, and, within the global sum approved in those annual estimates, they will have a great deal of freedom of expenditure. We hope that they will get the benefit, and we will see that they do get the benefit, of bulk purchase where necessary, but that does not mean that we shall take away their responsibility for making necessary purchases in order to do justice to their patients. (Col. 289.)

"... Moreover, the general maintenance of the hospitals and buildings is not to fall upon the Endowments Fund but upon the general Exchequer, as part and parcel of the business of the control boards. (Col. 290.)

"... When we take over the local authority hospitals we take over their rights and liabilities, which will be met out of national funds, and certainly are not to be a debt on endowments or brought into consideration on the distribution of

endowments. . . . As the Bill stands, this power of holding endowments lies only with the Regional Boards. However, it is an intention that that power shall be extended to the hospital management committees, and between now and the Report Stage we shall take the necessary steps to see that the power is vested in the hospital management committees." (Col. 294.)

Use of Endowments Fund (Clause 7)

Change.—The Minister introduced small amendments in Clauses 5 (5) and 5 (6) and added a new sub-clause 5 (7) to enable him to meet out of the Endowments Fund the liabilities transferred to him under the new sub-clause. "The rights and liabilities in the endowments are to be transferred in the same way as the endowments themselves. They are to be transferred, in the case of teaching hospitals, to the governors, and in other cases to the Minister. The rights and liabilities envisaged here are such things as contracts for the repair and maintenance of endowment property, the supply of goods in connexion with such property, liabilities that might arise out of the holding of securities, and things of that sort." (Cols. 297 and 300.)

Promise.—When members objected to the use of the phrase "managing any endowment," Mr. KEY said: "I am advised that it is all right, but I will certainly have another look at it. In the management of an endowment, if there is a fund there will be certain rights and liabilities that will arise out of the control of that fund." The amendments were agreed to. (Col. 300.)

Definition of Endowments (Clause 7 (8))

Change.—The definition added by the Government's amendment "covers all real property, such as house property, farm lands held as an investment, furniture, equipment, and other movable property that is used in connexion with such property. It covers, also, securities and other personal property held as investments, cash, bank credits, cheques, and so on; and, finally, it ensures, under a common type of covenant, annual payments for the benefit of the hospital concerned. As to ready cash, the effect is that on the appointed day, if the hospital shows a credit balance, then that balance has to be treated as an endowment, and is not to be transferred to the Minister in the ordinary way. As to debts owed to a hospital, which are likely to be small—for instance, payments may be due from paying patients—these will come under Clause 1, and will fall to be collected by the boards of governors or by the Regional Hospitals Boards. That may not be logical or tidy, but it is the best course to take from the point of view of administration." (Cols. 301-2.)

The Minister will consider any omission in the list that may be brought to his notice, and he will ascertain the real meaning of "equitable interest." (Col. 302.)

Trust Funds of Local Authority Hospitals (Clause 7 (9))

Change.—A clause has been added to make similar provision for local authorities, "because we have found that in some cases there are trust funds even in connexion with local authority hospitals. Therefore we think that in those cases such property should go to the board of governors or to the Regional Hospital Boards, as the case may be." (Col. 302.)

Property of Medical Schools Excepted from Transfer (Clause 8)

Change.—Additions made specifying the Welsh National School of Medicine, schools of a university other than the University of London, and institutions for the postgraduate teaching of medicine or dentistry. (Cols. 315-17.)

Intention.—Mr. KEY: "As far as the property held solely for medical or dental schools is concerned, that, of course, is dealt with by this Clause, but as far as property partly for school and partly for hospital purposes is concerned, that will be apportioned by regulations under Clause 6 (5). If difficulties arise, such as have been mentioned by my hon. Friends, they must be dealt with when the regulations come to be made." (Col. 318.)

Kinds of Hospital Property to be Transferred (Clauses 9 and 73 (2))

Change.—Addition made to cover (a) premises on which work of adaptation has begun; (b) new premises in course of

erection; (c) sites of old premises damaged and not restored; (d) premises not in use owing to war damage or undergoing extensive repairs. (Col. 323.)

Modification of Regional Areas (Clause II (1).)

Intention.—Mr. KEY objected to an amendment suggesting that the constitution of Regional Boards and definition of areas should be by regulation and not by order, as proposed in the Bill. He said during the discussion: "The view which I take of this problem is that the delimitation of these regional areas is a matter of the administrative function of the Minister, and that he should decide on the basis of information made available as a result of the hospital survey. He should do it after the necessary consultation with statutory and other bodies, as well as after consultation with individuals whose knowledge would be of assistance. But this is part and parcel of the Minister's administrative machine. It is to be his function to adapt it to the changing needs in the light of experience. So far as I am concerned—my right hon. Friend's mind may be a little different from mine on this matter—I cannot say that it is going to be possible to treat this matter in any other way than as an administrative function of the Minister. . . ."

"In working out this great hospital scheme, we shall have to have the power of modification and adaptation of the regional areas to the problems which arise, and there must be the facility for changing the areas and modifying them if experience shows that that would lead to an improvement so far as the administration of the service is concerned. It is quite definitely our opinion that that power must lie with the Minister from time to time to carry out what experience shows ought to be done."

Promise.—"I can say definitely that I know I am interpreting the Minister's mind correctly when I say that he regards this as an administrative function to be decided by him administratively, and that he should have the opportunity of adapting and modifying regional areas as experience shows to him to be necessary. The Bill places on the Minister the duty and responsibility of providing his hospital service and, since that is placed on him, he has to have the necessary power to settle these areas, and make modifications in them. He has said in this Committee that he will only do that after consultation with the appropriate bodies, local authorities, medical practitioners, and hospital authorities. Although they will all be brought into consultation, the determination of the matter must lie with the Minister. I cannot accept that there should be two orders, the area settled by one and the body constituted in the area titled by another. What I am prepared to agree is that we can make some modifications in the working of this Clause to ensure that the areas shall be specified in the order constituting the original Board." (Cols. 354-5, 359-60.)

Consultation on Modification of Regional Areas (Clause II (1))

Promise.—In rejecting an amendment requiring the Minister to consult local authorities and other organizations concerned Mr. KEY said: "I have a great deal of sympathy with what my hon. Friend said. My difficulty about an Amendment of this sort is that, as soon as it is said that there must be consultations with one particular interest, there will be a demand for including all sorts of other interests as well. To the extent that some are included, one excludes people with whom it may be necessary to consult. We fully agree that there should be these consultations, and, although I cannot accept the Amendment, I will see that the point that has been raised by my hon. Friend with regard to these consultations is met. I desire that there shall be a reference to the matter of consultations in the Bill, but I cannot undertake that they shall be limited merely to local authorities, or that it shall be specified what particular interests are to be consulted. What I wish is that before the areas are dealt with there shall be consultations with the people concerned." (Cols. 385-6.)

Hospital and Specialist Services on National Basis (Clause 12 (1))

Change.—Words inserted to make it clear that the Minister is not required to carry out his duties, in providing the hospital and specialist services, exclusively through the Regional Hospital Boards, but may determine to provide those services direct.

Intention.—Mr. KEY said: "There may be quite a number of new services to be developed which will need a national area for their development. For example, an existing service of that kind which I have in mind is the blood transfusion service, which was developed under central control during the war. It is intended to continue to organize that service upon that basis. We feel that it is necessary to have that wider scope for the purpose of ensuring careful supervision of technical methods in collecting and storing blood. This is for exceptional cases. I want to make it quite plain that the Minister can go outside the Regional Hospital Boards for the purpose of organizing specialist services." (Col. 402.)

Functions of Boards and Management Committees (Clause 12)

Intention.—Mr. BEVAN: "When we come to frame the schemes, the schemes will not be agreed to unless there is very considerable devolution of responsibility to the management committees. That is where we propose to secure it. The management committees may vary from place to place enormously." (Col. 420.)

Control of Epidemics (Clause 12)

Intention.—On rejecting an amendment for the appointment of the Medical Officer of Health as epidemic officer under the control of the Regional Hospitals Board, Mr. BEVAN assured the Member that "the liaison which will normally exist between every medical officer of health and the hospital services will provide all the unification necessary to deal with epidemics." (Col. 434.)

Regions (Clause 12)

Promise.—Sir H. WEBBE: "Is the Minister prepared to give the assurance that the London County Council area shall be a region?"

Mr. BEVAN: "No, I think the hon. Member should postpone his mischief-making until later." (Col. 435.)

Mr. BEVAN promised that if it was found that the drafting meant that regions would be only geographical areas it would be altered. (Col. 435.)

Staff Committees (Clause 12)

Intention.—Mr. BEVAN: "It is intended to have staff committees of all the health workers in hospitals. I hope, therefore, we shall not regard medical workers as different from any other workers." (Col. 436.)

Medical Officers of Health (Clause 12)

Intention.—Mr. BEVAN: "I can give no assurance that medical officers of health will be put in any special relationship with the health service. Medical officers of health will naturally carry on their responsibilities as at present, except in so far as they are modified by the provisions of this Bill, when it becomes an Act." (Col. 441.)

Freedom of Treatment (Clause 12)

Intention.—Mr. BEVAN: "The Minister will not accept the odium of giving directives about any particular form of therapy. That is a matter for the professional man, using the apparatus put at his disposal by the State, quite free and without any interference, directions, instructions, or prohibitions." (Col. 442.)

Hospital Management Committees (Clause 13)

Promise.—On the suggestion that if hospital management committees are empowered to receive gifts and legacies they will need legal status Mr. BEVAN said: "I will certainly look into that matter; but I am not proposing, apart from the very substantial concession already hinted at about the right of bequests, to give to the management committees anything further which may result in their becoming independent bodies. I believe that would cause a mutilation of the scheme, and a distortion that would give rise to anarchy." (Col. 443.)

Disciplinary Machinery for Specialists (Clause 14)

Promise.—In reply to an amendment to provide disciplinary machinery for dealing with complaints made against practitioners employed by Regional Boards, Mr. BEVAN said that he doubted whether there was any need for a tribunal for

specialists, because they were under a different kind of contract than general practitioners. "I think that when we draw up the regulations governing the conditions of service, reference will have to be made to protective machinery of this sort, and I think that will be the appropriate time to consider it. We want to have the kind of machinery which would meet the wishes of the persons concerned. It would be a different kind of machinery for different kinds of associations." (Col. 445.)

Advisory Appointments Committees (Clause 14)

Promise.—Mr. BEVAN promised to look into the meaning of section (2) (h), as it was objected that the appointment of a new committee every time a vacancy occurred would be cumbersome and unworkable. (Cols. 445-6.)

Research into Causation of Disease (Clause 16)

Change.—Mr. BEVAN: "I understand that a reasonable interpretation of the language of the Bill allows causation to be included, as well as prevention, but in order to make it doubly clear I am prepared to accept the Amendment." The word "causation" was accordingly inserted. (Col. 447.)

Blood Transfusion and Other Services (Clause 18)

Intention.—On the question of charges for blood supplies Mr. BEVAN said: "It is not proposed to make charges for those things which are already defined and exist to-day. It is not proposed, for example, to make a charge for blood to local authorities. The advances in medical science are such that new instances are being discovered, and we cannot expose ourselves to having to include everything which may be discovered, because then the whole scheme might break down. This provision is really protective." (Col. 448.)

Health Services provided by Local Health Authorities

Joint Authorities (Clause 19)

Change.—A drafting amendment has been made "to secure that local authorities can be formed into joint authorities for the purpose of carrying out health functions other than those which are mentioned in this Bill; such, for instance, as those connected with the Lunacy and Mental Treatment Acts and the Mental Deficiency Acts." When it was objected that the amendments made the clause too wide for a National Health Service Bill Mr. BEVAN said: "It would be too wide. It is only for the purposes of the Lunacy and Mental Treatment Acts and this Measure. If the provision goes beyond that we will certainly have a look at it." (Cols. 455-6.)

School Medical Services (Clause 19)

Intention.—During the discussion of an amendment concerning the application of Clause 19 to the London County Council a question of the medical inspection of school-children in the London area arose. Mr. KEY said: "Our scheme brings maternity and child welfare care in with that [school medical service], because it gives it to the same authority, and, therefore, will lead to a more efficient service. This scheme divorces maternity and child welfare service from the midwifery service, which is to be a service maintained and provided by the London County Council. Again, so far as the health centres are concerned, this scheme will divorce the centres that are provided for medical and dental care, and so on, from the provision of the necessary centres for the borough councils with their maternity and child welfare work. . . . It brings about the necessary machinery for co-ordination and co-operation between the services that are here being provided, and gives the necessary linking up of the interested bodies and parties to ensure that we get a really adequate service." (Col. 474.)

Later he said: "We are certain that, however much it may be necessary for local government boundaries to be dealt with and local government functions re-allocated, we cannot make the provision of this health service wait upon that reorganization of local government. We must provide our service and then find time and opportunity for that reorganization." (Cols. 476-7.)

Again: "It is being carried out in London as it is being carried out for everybody else; that is, the child welfare functions go with the educational functions and the medical inspection of school-children. The real point about this scheme

is that it applies to London exactly the same principle as it applies to every county council in the country." (Col. 485.)

L.C.C. Scheme (Clause 19)

Intention.—Mr. BEVAN: "What I intended to convey was that the London County Council would arrange a scheme by which there would be area committees in London on which the Metropolitan boroughs would be represented for the purpose of carrying out certain functions. But they would not delegate powers; they would have agreed responsibilities. It would not be possible under the Clause, or under the Bill anywhere, for a local authority, for a county or county borough, to delegate its powers, or any of its powers, to any of the smaller authorities. I believe that if we opened that door an avalanche would flow through it." (Col. 487.)

Joint Boards (Clause 19)

Promise.—Mr. BEVAN: "There will be consultations with the local authorities before the joint boards are set up. There are some health authorities in the country that are very poor, and it may be necessary to have some joint undertaking before they will be able to discharge their functions properly under the Bill. Certainly, of course, there will be consultations with them before a joint board is established." (Col. 490.)

Appointed Day (Clause 19)

Promise.—Mr. BEVAN promised to look into the interpretation of the Clause as it affects the position on the appointed day of the functions of health authorities other than the L.C.C. and county councils. (Col. 491.)

Consultation on Local Schemes (Clause 20)

Promise.—On an amendment to require that local health authorities' proposals shall be submitted not only to voluntary organizations and the Executive Council but also to the minor local government authorities within the area Mr. BEVAN said: "Some of the voluntary organizations will be consulted over the personnel of many of these services. That is why we are doing it; but these authorities would not be. I do not want to put unnecessary language into the Bill. What is the use of notifying if no consultations take place after notification? However, I do not want to resist the hon. Gentleman and I will look at it and, if it proves to be practical, certainly I will do it." (Col. 498.)

Area of Regional Hospital Board (Clause 20)

Promise.—Mr. BEVAN said it was not the intention of subsection 2 (b) that a local health committee should be wholly comprised in each regional board. He would look into the wording. (Cols. 490-500.)

Health Centres (Clause 21) (see also p. 23)

Intention.—The following extracts are from Mr. Bevan's reply to a long general discussion on health centres. (Cols. 522-32.)

Need for: "There is a great deal of controversy about health centres. As I understand it, there is no controversy about the necessity for establishing them." (Col. 522.)

Experiment: "It is obvious that we shall have to have some experimentation. Nevertheless there is no experimenting with the initial idea; there is only experiment as to how it is to be carried out—for instance, with regard to building. Opinions have been taken as to units of population. If there is a health centre serving a too large unit of population, it may be too far from some patients' homes. Nevertheless it must serve a fairly large unit of population if we are to be able to afford to have diagnostic apparatus in the health centres. We cannot have expensive medical apparatus in every street, although, after listening to some of the enthusiasts of the medical profession, one would imagine that before long the whole country would be nothing but one large health centre and doctors' houses. We are looking forward to a healthy population. What we are striving to do is to create a health service which will make people healthy, and not keep them sick. Unless we are careful we may create a nation of hypochondriacs.

"That is why it seems to me so necessary to give a great deal more attention than has been given to the preventive side of medicine. At every large health centre there should be

opportunities for doctors to talk to children, to talk to mothers, and to talk to separate sections of the population about their particular problems. If we can get a stream of healthy people attending the health centre it becomes a health centre; but if we merely have morbid cases going to the health centre it becomes a morbid centre. So the more diverse the services that can be rendered by the centre, the better the atmosphere of the centre will be. One of the chief drawbacks of the out-patients departments of hospitals is that they are most depressing affairs. Everybody in them is sick; everybody has something wrong; there are there all sorts and shapes and sizes of people sitting on squalid hard benches for hours, waiting for tired doctors to attend them. It is an appalling atmosphere. Indeed, some of the out-patients departments of hospitals that I have seen are reminiscent of descriptions by Charles Dickens.

"It seems, therefore, that we have to insist on health centres being adopted generally, but what we have not been able to make up our minds about is whether we are to have health centres providing a considerable variety of services, or rudimentary consulting centres nearer to people's homes where five or six or more general practitioners attend with comparatively rudimentary apparatus, from which centres the doctors can send their patients for more extensive examination, if necessary, to the health centres." (Cols. 523-4.)

Rural Areas: "We shall not be able to provide, in the rural areas, a very large number of fully fitted health centres. That does not mean there will be no health centres in the rural areas or that the rural areas ought to be denied them. It merely means that country people may have to go rather long distances in order to attend the more ambitious health centres; and yet that doctors will be able to see them in small centres where the apparatus is more rudimentary."

LORD WILLOUGHBY DE ERESBY: "Would not one way out of the difficulty be to encourage doctors to develop their own surgeries?"

MR. BEVAN: "We do not want them to do that. We want them to get away from their surgeries and mix with each other rather more."

LORD WILLOUGHBY DE ERESBY: "The right hon. Gentleman said there had to be smaller consulting centres in the smaller rural areas. I should have thought that the easiest way would have been to develop what are already there, the doctors' surgeries."

MR. BEVAN: "We should be very ready, indeed, to encourage larger groups. We want more partnerships of that sort, but the question is whether doctors should see their patients in their own surgeries, or whether the local authorities should establish centres." (Cols. 524-5.)

Child Guidance Clinics: "The more healthy the health centres become, and the less they become merely sick centres, the more that kind of service can be developed." (Col. 525.)

Duties of Local Authorities: "I was asked whether or not it would be a desirable thing to allow local authorities in the meantime to experiment themselves. If we are to have a health service, we must have a national service, and we could not permit backward local authorities to deny the citizens in their areas the health facilities available elsewhere. Therefore it must be a duty; but, of course, the extent to which we can impose the duty and insist on its being carried out depends on the extent to which we can provide facilities." (Col. 525.)

Date: "There are places where health centres can be established quite quickly. I do not suggest that this can all come into operation on the appointed day, or that one might wake up one morning and find magnificently appointed, impressive health centres in all parts of the country. This will have to be a growing service, developing from year to year, and adapted from year to year as our experiences dictate." (Col. 525.)

Promise.—Specialist Services: The Minister would not approve schemes unless they provided accommodation for specialist services. "I am advised that this Clause and the other Clauses, taken together, provide the Minister with all the authority he needs. If they do not, we will amend the Bill, so as to make it so on the face of the Bill, because that is our intention." (Col. 526.)

Intention.—Dental Clinics: "Dental clinics will be at the health centre, because we do not want dental clinics to be separated from the rest of the health services." (Col. 526.)

Opticians and Ophthalmologists: "If facilities were available and if there were enough ophthalmologists, it would be desirable that anybody who felt he or she had something wrong with his or her eyes should see the ophthalmic surgeon first. I should have thought that would have been generally agreed." (Col. 527.)

Responsible Authority: "There was a point made about the provision of health centres being made by the Regional Board and not by the local health authority. I could not agree with that. The Regional Boards are much too wide. It would be administratively impossible. It was suggested that the Regional Boards should provide the health centres and that the local authorities should use them. That would be silly, because the local health authority provides the health centres and the Regional Board and the general medical practitioner use them. I should have thought it was far better for the local authorities to have these functions. We are taking away from them their hospital functions. It seems to be a very wise provision." (Col. 528.)

Professional Secrecy: "I agree there are large numbers of people who want to be assured that there will be complete privacy for any confidences they may repose in their doctor. There is no intention of mutilating that tradition. . . . I agree that the medical history should go from one professional hand to another, and that it should not be available for secular scrutiny. . . . It would be very undesirable if the impression got abroad that the confidence one reposes in one's doctor was entered into a book by someone else and that other people had access to that information. I hardly think that would arise, but I am glad to give assurances that we shall do our best to prevent that happening." (Cols. 528-9.)

Child Guidance Clinics: "There is a great shortage of trained psychiatrists. I agree that they can be trained, but there are large numbers of people who have learned the nomenclature of psychoanalysis and are masquerading as psychiatrists. While I said that I agree that it is necessary for skilled guidance to be given at the health centre, let us see that it is skilled guidance. That is desirable. Subsequently the medical service of the schools will be assimilated into the national health service, and, as that is done, that branch of the national health service can be expanded." (Col. 529.)

Tuberculosis Clinics: "Tuberculosis clinics would not necessarily be at the health centre. They would be in some cases, but not in every case. In many cases they would be at hospitals." (Col. 532.)

Ambulance Services (Clause 27)

Change.—Words inserted to make it clear that the duty of the local authority to provide ambulance or other similar transport applies only when the need exists for that transport. (Col. 559.)

Change.—Words omitted to make it clear that the duty to provide the necessary ambulance and transport lies with the authority in whose area the need originated. (Col. 559.)

MR. BEVAN: "I imagine it would be the duty of the local health authority in the area concerned to have no regard to the origin of the citizen, but merely to his need, and to provide him with the necessary facilities. It would, indeed, be a breach of trust if it did not do so. Of course, it must be remembered that the hospitals themselves will find it necessary to have a rudimentary ambulance service, because there will be movement between hospital and hospital." (Col. 560.)

Domestic Help (Clause 29)

Change.—Wording altered to remove limitation of domestic help to cases where the children are under 5 years of age. (Col. 578.)

Date of Operation of Act (Clause 30)

Intention.—**MR. BEVAN:** "The Committee will appreciate that the administrative work that will remain to be done after Parliament has passed this Bill will be enormous, and that quite a considerable period of time will elapse before the whole of the scheme is in operation. Even after that the full service will depend upon its being properly manned, and, as everyone here knows, we are short of some of the requisites with which to man it—we are short of sufficient doctors, sufficient specialists in particular, sufficient dentists, and, with regard to a very

hospital boards, but may determine to provide those services direct.

mentally for dealing with complaints made against practitioners employed by Regional Boards, Mr. BEVAN said that he doubted whether there was any need for a tribunal

vital provision in the Bill, sufficient health centres. It will take some time before health centres are available, and there has been some doubt as to whether we ought not to postpone the provision of health centres until we are able to house them in new buildings. Some say it would be a very bad thing to start in inauspicious conditions by housing health centres in old buildings. I incline to the view that until we are able to build health centres of a new and agreeable character we shall have to adapt old buildings; otherwise it may be a long time before they can operate.

"It is intended that the Bill should come into operation on April 1, 1948. I do not think it would be possible for us to introduce it before that. It must be synchronized as far as possible with the National Insurance provisions, because we want to be able to provide the services under this Bill when persons have paid their contributions and are entitled to receive them. Meanwhile it will come into operation in different stages. As I have said before, I hope to appoint Regional Boards quite quickly, and the local authorities become authorities under the Bill as soon as it is passed. I would like to be more precise as to the different dates and stages at which the scheme comes into operation, but, if I tried to be so at this moment, I am certain that the dates I gave would have to be adjusted in the light of subsequent experience. I will look at the point raised by the right hon. Gentleman and make quite certain that the elasticity is not interfered with by the language of Clause 30." (Cols. 581-2.)

General Medical, Dental, and Other Services

Executive Councils (Clause 31)

Promise.—The Minister was asked for an undertaking that he would set up the full type of Council in the first instance, and only after experience has shown that some variation is necessary, and after consultation with those who have had the experience, will he introduce the variation.

Mr. BEVAN replied: "I will have a look at it and see whether it is possible to do what has been suggested. We are a bit frightened. It may be that in certain circumstances the interests which are to be represented upon the local Executive Council may be more than adequately or inadequately represented. We have no concrete case in mind, but there is a possibility of that arising, and it would be necessary in order to secure proper representation in some area, for some parts of it to be more weighted than other parts. That is the sort of condition we had in mind. Take a very rural area, for example, in which the representation of certain interests will not be sufficiently provided for under the balanced constitution of the Executive Councils in other parts of the country." (Cols. 586-7.)

Local Medical Committee (Clause 32)

Change.—The term "Local Medical Committee" has been substituted for "Medical Practitioner Committee" in view of similarity of names and initials of Medical Practices Committee and Medical Practitioner Committee. (Col. 588.)

The Minister undertook to consider a similar alteration in the title of the Dental Practitioner Committee. (Col. 589.)

Choice of Doctor (Clause 33)

Promise.—Mr. BEVAN said the language of the Clause did not prohibit an individual who had been rejected by one general practitioner being accepted by another. The regulations would make it clear. (Col. 590.)

Method and Amount of Remuneration (Clause 33)

Intention.—Mr. BEVAN: "I must at once resist any attempt to try to get me to put the method or amount of remuneration of the general practitioner in the Bill. I think that is much better done by regulation. Indeed, I believe the doctors would prefer it to be done in that way. It would be a most extraordinary situation if, every time variation in circumstances took place, a Bill was necessary to modify the remuneration and method of remuneration of the doctors." (Col. 594.)

Method of Remuneration (Clause 33)

Intention.—Mr. BEVAN: "I am firmly convinced that it is necessary to have an element of basic salary in the doctors' remuneration. . . . Some element of hedonism is necessary,

with some element of punishment and of reward. That is the reason I have come down on the side of capitation as part of the remuneration. Furthermore, I found it very difficult to reconcile the free choice of doctor with the complete abolition of capitation. It is very difficult to do it. If one has full salary, then one has to allocate patients among the doctors and doctors among the patients. That would result in an unhealthy relationship between patient and doctor. Therefore, we found it necessary to have capitation. When we draw up the regulations, I think we shall have to have a ceiling to the capitation, and it may be necessary to introduce a number of other modifications. These will have to be subjects for negotiation with the representatives of the profession. I am certain that hon. Members would regard it as particularly arbitrary for a Minister in a Committee to lay down *obiter dicta* as to what the salaries should be without first of all giving the representatives of the profession, or the workers concerned, an opportunity of stating their views.

"I am in consultation with representatives of the profession at this moment on these matters. I prefer that these consultations should reach a more advanced stage before I myself express any definite opinion. . . . There will be circumstances where it will be necessary to weight the basic salary to get sufficient doctors into the under-doctored areas." (Cols. 595-6.)

Variation of Capitation Fee (Clause 33)

Promise.—Mr. BEVAN: "I have an entirely open mind as to the desirability of declining the capitation rate, and I am prepared to look at it again. That is not a matter of fundamental principle; it will have to be re-examined in the light of discussions with the profession." (Col. 618.)

Position of Assistants (Clause 33)

Intention.—In reply to an amendment designed to elicit from the Minister a statement on the position of assistants in general practice Mr. BEVAN said: "I think it is a most desirable way of introducing a doctor to general medical practice. But, at the same time, we cannot give general practitioners an unrestricted right to take on as many assistants as they like, because that would interfere with the proper distribution of doctors. It is intended that there should be no restriction on the rights of general practitioners to have assistants in areas where the Executive Council agree that assistants can be employed because the area is not over-doctored. . . . Assistants would not be on the list, but they would be registered doctors. The provision of assistants to principals would be one of the factors to be taken into account by the Executive Council and the Medical Practices Committee in deciding whether an area was sufficiently doctored, over-doctored, or under-doctored. . . . It would not be reasonable if a doctor took on an assistant, who remained with him for some time, for the assistant to go on the list for that particular area. Otherwise he would be using his association with his principal in order to establish his own practice. That would be undesirable. How far restriction should apply is a matter we shall have to discuss in detail with the profession. I have already had preliminary discussions about it. They are seized with the difficulty. It is a question of deciding what area of restriction should be imposed." (Cols. 619-20.)

Distribution of Practitioners (Clause 34)

Intention.—Mr. BEVAN: "Even if it were not necessary for the proper distribution of the general-practitioner service to abolish the sale and purchase of practices, I should still do it, because it is an intrinsic evil. . . . It means the bartering of the patients themselves." (Cols. 631-2.)

"The machinery [under Clause 34] will be of invaluable assistance to the young doctor. . . . He will receive information from a central pool as to what areas he can go to at once. He will know the areas where he will not be acceptable in the public service. He will know the Executive Councils which have the authority to appoint more doctors, and he will, therefore, know at once where he can go, and he will know it within a day. He will not have to 'fumble around' and advertise or ask his friends. He will know at once. Therefore, it seems to me that the machinery which we are establishing will work out to the great advantage of the doctors themselves.

"What then happens? In practice, this is what will occur. The local medical committee will make suggestions to the local Executive Council as to a particular doctor. It may happen that they want to take on a partner; and, if you are going to have group practices in the health centres, the doctors themselves ought to have some chance of determining their new colleagues. So what happens is this: There is a vacancy. The Executive Council notify the local doctors' committee that there is a vacancy. They may say, 'We think So-and-so will be all right, and we will make that recommendation to the Executive.' The Executive may or may not accept that recommendation, but, as I have said, half the representation on the local Executive will be professional. Therefore the point of view of the local doctors' committee will have very great weight with the tribunal, and they will, therefore, recommend to the Medical Practices Committee the persons to be appointed. In fact, the individual doctor will be selected by the local Executive, and not by the Medical Practices Committee. It is necessary for the central committee to confirm the appointment, because that removes the actual confirmation from the local area, where sometimes the influences are not altogether of the right kind.

"So we get three things which we are anxious to keep. We get the doctors themselves influencing the appointment of their new colleagues; we get the local Executive, which is going to have the supervision of the medical service in that area, appointing; and we get the central committee confirming the appointment, and, in confirming the appointment, being able to satisfy themselves that all the considerations leading to the appointment are proper ones. I should have thought that this arrangement was highly desirable. It satisfies every principle of democratic practice and wholesome administration. In course of time, as the general practitioner service is redistributed over the country, this machinery will begin to work more and more smoothly and with less and less interference, and it may be that some of it will pass almost into desuetude." (Cols. 633-4.)

"I hope that individual selection by individual doctors will progressively disappear, and that collectively the profession will make the recommendation, and not an individual doctor." (Col. 640.)

Procedure for Appointment (Clause 34 (3))

Intention.—Explaining the procedure for appointment by the Medical Practices Committee Mr. BEVAN said: "In order that the Medical Practices Committee may have the right of intervening when improper action has taken place they must have the right of appointment. . . . A number of persons make application for a particular position, and recommendations are made to the Medical Practices Committee, which makes the appointment, which is, in fact, a selection . . . from the applicants."

The Executive Council has performed all the functions of the Medical Practices Committee, but in order that the Medical Practices Committee may have the power of selection they must have the right to refuse an appointment. The language of the Clause does not carry out what I am saying, we will look at it and see that it does, but what we really intend to do is to act as sensible persons." (Col. 657.)

Change.—The following addition was made at the end of the Subsection: "Before selecting any persons under this subsection the Medical Practices Committee shall consult the Executive Council concerned, and that Council shall, if a Local Medical Committee has been formed for the area of the Council and recognized under the last but one foregoing section, consult that Committee before expressing their views on the persons to be selected." (Col. 658.)

Appeals against Decisions of Medical Practices Committee (Clause 34 (7))

Promise.—Objection was made by a Member that the subsection might deprive the public of services which are urgently required. "When the Medical Practices Committee has already selected somebody, the people selected will not be able to start practice and get on with the job, in which their services may be very much needed, if an appeal has been made, but must wait until it has been heard, and a decision given before they may go into practice."

Mr. BEVAN replied: "I should have thought . . . there was no real danger. If there was any danger I would deal with it." (Col. 658-9.)

Family Associations with Practice (Clause 34)

Intention.—On an amendment suggesting that the Medical Practices Committee and Executive Councils should take into consideration the tradition of family association with an area and the views of existing partners Mr. BEVAN said: "This is the sort of thing that the local medical committee would take into account when making its recommendation to the Executive Council. I do not think we should give a special statutory value to family relationships. Indeed, as one of my hon. Friends pointed out yesterday, it is very often desirable that there should not be too much inbreeding in some local areas, and that we should get more infiltration from outside. Therefore I would not like to put into the Bill an insistence that some special consideration should be given in such cases. But the hon. Member himself said—and I agree with him—that there is a tradition, and that tradition would inevitably have its influence on the selection. I do not want to have to give directions to local Executive Councils about this, because it seems that it is just the sort of thing which they ought to be free to do, and the less centralizing there is about it the better. The Minister ought not to tell the local Executive Councils what grounds they should consider in making an appointment, because that would give undue weight in favour of some against others. I am sure the hon. Member realizes that the point will be taken into account." (Col. 660.)

Partnerships (Clause 35)

Promise.—The first of a series of amendments put forward with a view to "making this Clause, which is an enormous and unparalleled revision of the criminal law, fair and certain and not obscure and unfair," sought to preserve the position of partnerships in which one or more of the partners did not accept service under the National Health Service. Mr. BEVAN said: "Where a partner has not got a panel, if he is in partnership with doctors who have got a panel, I am advised that nothing in this Clause inhibits that partner from selling his practice. The right hon. and learned Gentleman said that a partnership is a corporate affair, residing, not severally in the individual partners, but as a whole. I am advised that it is not this case here; that we are here dealing with individual doctors, and it is only the individual doctors with whom we are concerned. If a doctor is not in the public service, if he has not got a panel, nothing in this Bill prevents him from selling his practice if he can find a buyer. . . . If I thought the effect of this language would be to bring about a general dissolution of partnerships, we would try to seek protection against that."

I am advised the Clause has no such effect." The mover of the amendment then read a Counsel's opinion. The mover of the subsection is amended the only way I can see by which this difficulty could be overcome would be by dissolution of the partnership before the appointed day. Mr. BEVAN then replied: "I can assure the right hon. and learned Gentleman that if the language of the Clause would have that effect, then the Clause must be amended. I will certainly have a look at it." (Col. 670-2.)

Penalties (Clause 35 (2))

Promise.—In order that courts of summary jurisdiction might not be given extensive powers on matters of great importance an amendment was submitted to the effect that courts of summary jurisdiction should have no more power than to inflict a fine not exceeding £100. Mr. BEVAN replied: "It seems to me that where the higher penalties are involved there is a good case for the case being tried by a court with a jury, and I think there is considerable substance in that contention. The right hon. and learned Gentleman might lead me to move an Amendment at some subsequent stage. I do not wish the penalties to be too light. . . . These cases will occur on the part of doctors who have either entirely misrepresented to the Medical Practices Committee what they have done, or have neglected to protect themselves by getting a certificate from the Medical Practices Committee, or persons obviously with felonious intent." (Col. 673.)

"I am disposed to say at present that all cases which are not merely cases involving a small fine go before a jury." (Col. 674.)

Time Limit for Proceedings (Clause 35 (3))

Promise.—In reply to an amendment providing that proceedings should not in any event be brought more than two years after the date of the commission of the alleged offence Mr. BEVAN said: "Obviously, as a consequence of a promise given previously [see preceding note], this subsection is entirely altered. This applies to cases brought before courts of summary jurisdiction, and if they are not to come before those courts I really think we ought to get on with the next business." The amendment was accordingly withdrawn. (Col. 677.)

Assistants and Prohibition of Sale of Practices (Clause 35 (5c))

Change.—The words "having regard to the circumstances at the time when the remuneration was fixed" were inserted to extend to the employment of assistants the same safeguard as applies in the case of partnerships. (Col. 701.)

Offences Relating to Remuneration of Assistants (Clause 35 (6))

Promise.—The mover of an amendment to substitute "if" for "unless" complained that it was unfair to place the onus of proof on the accused person. Mr. BEVAN replied: "This Clause was very difficult to draft, because we are seeking to find a whole series of offences to protect the whole scheme. I will certainly have a look at the Clause to see if any of the fears expressed at the last meeting of the Committee are justified, and whether we can remove any cause for apprehension before the Report stage. I think I should be justified in resisting this Amendment, but I will certainly have a look at it. How is a prosecution to know what was in contemplation? Surely, in that case it is reasonable to put the onus of proof on the accused person, because there is a considerable subjective element in the whole matter." (Col. 703.)

Sale of Instruments and Equipment (Clause 35 (7))

Promise.—The mover of an amendment complained that "if any retired doctor sells his own instruments or equipment to the succeeding doctor, in contemplation of the succeeding doctor coming into his practice, he commits an offence, however fair the price may be."

Mr. BEVAN replied: "I am advised that the fears of the right hon. and learned Gentleman are quite groundless, but if they have any substance I will re-examine the whole matter, and make an alteration, if necessary. . . . I understand that the Amendment would not do what the right hon. and learned Member suggests, but I will certainly see whether any alteration is necessary." (Col. 708-9.)

Certification of Transactions (Clause 35)

Change.—Mr. BEVAN moved an addition to the Clause to provide for the certification of transactions by the Medical Practices Committee. He said it was "a strong protective provision which we wish to insert into the Bill in order to remove some of the fears which doctors legitimately have, and of which I make no complaint. Without some protection of this sort the Clause is rather frightening. I believe that with this it ought to be possible for the Clause to work without penal consequences of any gravity. I am sure that the doctors' professional organizations will call the attention of their members to this provision. The Medical Practices Committee will issue a certificate, and that certificate will be a defence in itself." (Col. 709-10.)

Promise.—During the discussion amendments to the amendment were proposed, and Mr. BEVAN promised to look into certain points:

(i) "There ought to be some way of conveying to the applicant for a certificate to which part of the contract exception has been taken. I will look at that part of it, but I cannot accept the imposition of a time limit. I agree that these cases should be expedited." (Col. 713.)

(ii) "It seems to me it would be perfectly proper for the Medical Practices Committee to take the new disclosed fact into account for the purpose of invalidating the certificate. We might do something on those lines" (Col. 719.)

(iii) "I will examine that"—i.e., the suggestion that Subsection (11) in the Minister's amendment was unnecessary, because it created the offence, and put a person on trial when he ought not to be put on trial at all. (Col. 720.)

(iv) "We want to avoid ambiguity and to make legislation the vehicle of our intentions. Therefore we shall examine the whole thing with a view to seeing whether what has transpired in the Committee discloses a weakness in the language of the Clause, making it necessary for us to amend it. I accept what the right hon. and learned Gentleman has said, that unless we can make our intention more specific the existing partnerships may be very seriously affected, and they may not know what to do. Therefore, before the Report stage we shall examine the language of the Clause, particularly with a view to its relationship to partnerships." (Col. 722.)

(v) Mr. Bevan also promised to look into the meaning of the word "transaction" in his amendment. (Col. 722.)

The amendment was then agreed to.

Compensation (Clause 36)

Change.—An amendment was made to make clear that the sum of £66 million related to practitioners in Scotland as well as England and Wales. (Col. 724-6.)

Intention.—Mr. KEY outlined at this stage the three steps which had to be taken: "First of all, there is the question of the total compensation to be paid. That is put down at a figure of £66 million, on the supposition that the number of medical practitioners joining the service will be 17,900. If, however, that is not realized and the number is smaller than that, no alteration will be made in the sum total of £66 million, unless the number joining falls below 17,900*. If it falls below that number, then the total of £66 million will be reduced by 1/17,900th for every practitioner below the figure of 17,900*. Therefore, that will give the total figure of £66 million if the number is realized, or a smaller figure if it is not. That is the first step that has to be taken to get the figure for Great Britain.

"The second step to be taken is that of deciding the apportionment of that sum between the services in England and Wales and in Scotland. That will be decided upon the question of the relative losses of the people involved in these two sections. Then the third step, so far as we are concerned here, is taking the portion that comes to England and Wales and deciding upon its proper distribution. That proper distribution will be according to regulations, which will be made after consultation with the profession. What is required to make quite certain and to clarify this Clause is that the sum to be decided in the first place is that to be decided for Great Britain as a whole." (Col. 724-5.) [* This is a misprint in both cases for 17,700.]

Number of Principals (Clause 36 (2))

Change.—The definite figures, "seventeen thousand nine hundred," and "one-seventeen-thousand-nine-hundredth part of sixty-six million pounds," have been substituted for "the prescribed number" and "a prescribed amount." (Col. 726-7.)

Date of Payment of Compensation (Clause 36 (3))

Promise.—Mr. BEVAN rejected an amendment proposing that compensation should be paid in all cases forthwith or as soon as practicable after the appointed day, and, on being pressed to state his intentions with regard to cases of hardship, he said: "It is very difficult for me to go further at the moment. I consider it to be desirable that such matters as this should be discussed with representatives of a profession, and that is what I propose to do. I think it would be unwise to consider a number of hypothetical cases now. This is a matter of practical administration. No one desires to withhold money from people and cause great hardship to them. I do not think that very much money will be involved. It is pure guesswork as to how much of the £66 million will be paid out earlier than the normal dates. The amount will be determined by the Regulations." (Col. 731.)

In reply to a question whether a practitioner, having withdrawn from practice on health grounds and received compensation, and having recovered after a year's rest or treatment, could apply for a post in an under-doctored area, Mr. BEVAN said: "I should have thought so, but I would like to consider the matter further before giving a specific reply." (Col. 732.)

*Practitioners Dying or Retiring before Appointed Day
(Clause 37)*

Promise.—Asked about the sale of the goodwill of practices of doctors who die just before the Act comes into force, Mr. BEVAN said: "I have it in mind at the present time to insert a date, which I think would cover the points raised by hon. Members, on the Report stage. . . . There is an argument for putting in a date from the point of view of some of the hardship cases now arising. The actual date is not yet fixed, but I propose to put it in on the Report stage." (Cols. 734-5.)

Pharmaceutical Services (Clause 39)

Intention.—Mr. BEVAN: "Arrangements will be made in the rural areas for doctors to provide medicines; otherwise the whole thing would break down." (Col. 738.)

Dental Services (Clause 40)

Intention.—Mr. BEVAN: "A committee will be established in consultation with the profession, on the lines of the Spens Committee, for the purpose of advising on methods and scales of remuneration for dentists. I think it would be as well if we awaited the recommendations of that committee before pronouncing judgment. Obviously it will be necessary to have some form of attracting dentists to go into unremunerative areas. Whether that should take the form of higher scales, or a subsidy, as in the Highlands and Islands Scheme, is a matter for further consideration." (Col. 739.)

Promise.—He also promised to discuss with representatives of the dental profession the question of the approval of estimates before treatment was undertaken. (Col. 740.)

Distribution of Dentists (Clause 40)

Intention.—Mr. BEVAN: "It will be possible for dentists to appear in the lists of more than one Executive Council. Therefore they could take patients from other areas." (Col. 742.)

Employment of Dental Mechanics (Clause 40)

Promise.—Mr. BEVAN: "We shall have to consider that in the general inquiries as to how we are to give such supplementary assistance to the dentist as will spread the dentists over a larger number of the population and enable them to give more treatment. I agree . . . that it would be desirable that, when regulations are drawn, they should not make it necessary to get estimates for emergency operations and things of that sort." (Col. 744.)

Sight-testing Opticians (Clause 41)

Intention.—Mr. BEVAN: "I think that all hon. Members agree that the ideal system would be that anyone sent to a doctor, unless they have something wrong with their eyes, should first pass through the sieve of what I call the eye specialist, because he is the person who is capable of looking at the condition of the eyes and of determining not only whether there is something wrong with them but whether there is some other morbid condition of the body. . . . The eye specialist . . . will not waste his time doing refraction work. . . . It would be quite absurd not to make use of the services of a qualified optician; in fact we propose to make use of his services to the utmost extent, and the apprehensions that exist among them at the present time are based upon a misunderstanding of our intentions. . . . We want to encourage good people to come into the profession. . . . What we desire is to regularize arrangements by which the properly qualified eye-testing optician is identifiable. With a view to that, the representatives of the eye specialists and the eye-testing opticians are to meet at my invitation next week for the purpose of discussing. I hope in terms of cordial co-operation, what shall be the relative status of both sections. We shall then be able to employ this in the Bill, which is drawn widely so as to give us powers to do so as time goes on.

"It is perfectly true that we shall have refractionists in the large health centres, and I envisage the system as being one that is extremely fluid, where we shall have the eye specialist, as such, centred on the hospitals, but moving quite freely between the health centres and the hospitals without any difficulty at all." (Cols. 754-5.)

*Supplementary Provisions**Tribunal (Clause 42)*

Intention.—In a long speech resisting an amendment to provide a right of appeal to the High Court Mr. BEVAN pointed out that: "We are not discussing here whether a man has been guilty of unprofessional conduct. What we are discussing here is whether a person who had contracted to carry out certain duties carries them out satisfactorily to reasonable people. . . . It seemed to me that the existing procedure was not enough, that the Minister ought to put between himself and the local Executive Council another body." (Col. 770.)

After describing the procedure through the local Executive Council, the Tribunal, and the Minister, he said: "The possibility of injustice being committed against a person after these three steps of investigation, I will say, is negligible." (Col. 771.)

"We cannot admit that the courts should interpret whether the doctor has, in fact, been a good servant to the people." (Col. 774.)

"I am satisfied that the doctors themselves would be far worse off, because, if an offence were committed in one area, I am providing that it would only be necessary to move the doctor from that particular list. He could go elsewhere, whereas if he went to the courts the case would be publicized throughout the country." (Col. 774.)

The effect of the voting was that Subsection (4) providing for an appeal to the Minister was omitted, but the amendment to insert words to provide for an appeal to the High Court was defeated. Saying that the mover of the amendment had succeeded in persuading the Committee that there should be no appeal at all, Mr. BEVAN stated:

Promise.—"On the technical aspect of the matter there is no reason why we should not get the Clause as it is, and then subsequently I can consider what other steps should be taken at a later stage of the Bill to remedy the unfortunate consequence of the Pyrrhic victory of this morning." (Col. 791.)

Disqualification in Scotland (Clause 42)

Change.—An amendment was made "to bring about reciprocity with Scotland in the matter of disqualification of practitioners."

"Where practitioners are disqualified from inclusion in the list in Scotland—not in one or two places—they can be disqualified from the list in England, but if they are disqualified in only one or two places in Scotland they will not be disqualified from the list in England. It has to be total disqualification." (Col. 791.)

Publication of Decisions of Tribunal (Clause 42 (6))

Change.—An addition was made to provide in regulations for the publication "of the imposition and removal of any disqualification imposed by virtue of the last foregoing subsection." (Col. 792.)

Evidence on Oath (Clause 42)

Promise.—Mr. BEVAN said it was proposed to make provision by regulation for evidence to be taken on oath. (Col. 793.)

Legal Representation (Clause 42)

Promise.—Mr. BEVAN: "I do not want to put the legal representation in the Bill at the moment, because that might appear to preclude other forms of representation that plaintiffs might desire. It does not always follow that a plaintiff wants to be represented by a lawyer. It is his right to choose. He may wish to have a friend. So I propose by regulation to provide that evidence shall be taken on oath, and that persons shall be represented by a legal representative. . . . I will look at it. If it is absolutely essential, certainly we will put it in, but my present advice is that this can be better done by regulation." (Cols. 793-4.)

Range of Penalties (Clause 42)

Promise.—Mr. BEVAN: "It is proposed by regulation to enable other forms of discipline to be imposed in addition to that of being removed from the list, because, obviously, there must

or minor offences for which smaller penalties would be appropriate, and provision will be made for the Executive Council and the Tribunals to impose them." (Col. 793.)

Powers of Minister where Services are Inadequate (Clause 43)

Intention.—In reply to an amendment requiring the Minister to consult the appropriate committee or Executive Council, Mr. BEVAN said the provision was unnecessary. "Obviously, where the service has broken down the Executive Council would consult the representatives of the services affected before making any proposals. It would be extraordinary if they acted *in vacuo*, but at the same time we do not want to tie the Executive Council always to formal discussions, because it may be necessary to take urgent action in a particular instance." He also referred to Clause 32 (2). (Col. 795.)

Emergency Ophthalmic Services (Clause 46)

Intention.—Mr. BEVAN: "It is not intended that the emergency ophthalmic services shall be based on health centres, because they are a temporary expedient. Subsequently long-term ophthalmic services will be based on the special services. Whether eye-testing opticians can be provided at the health centres will be a matter for experience to decide." (Col. 809.)

Health Centres (Clause 46) (see also p. 17)

Intention.—**Character:** Mr. BEVAN: "I hope there will be considerable diversity, and that from that we shall be able to pick the features of the most successful places and embody them in general practice. If there is to be this diversity I would be foolish now to give any precise indication of what I think the health centres would be like. I said some time ago that it would be necessary, in some instances, to have constellations of health centres, with minor ones servicing a central one with much wider polyclinical facilities." (Col. 812.)

Remuneration of Doctors: Mr. BEVAN: "Doctors are allowed quite substantial expenses on account of having to provide facilities at their houses, and that expresses itself in the standard of remuneration. If we are to provide them with those facilities at health centres, and leave their remuneration untouched, it is a substantial accretion to their remuneration. If we propose to do that, then that must have a bearing on the standard of remuneration. Unless we are careful we can be stamped in all kinds of directions." (Col. 812.)

Rent: Mr. BEVAN: "Doctors will not be expected to pay an economic rent for the health centre. That itself provides an attraction to go there. I should have thought that before very long, if we can provide good health centres, with proper facilities, the doctor's wife would have had something to say about it. . . . The Executive Council will not be paying an economic rent for the health centre, because we are making it a duty on the health authority to provide the health centre. There will be an apportionment between them for the facilities they are given. The local authority will be enjoying advantages from the health centre, such as maternity and child welfare and other services." [Promise:] When it was objected that this was not so according to the drafting Mr. BEVAN promised to look at it again. (Cols. 812-13.)

Residence of Doctors in Area: Mr. BEVAN: "It will be difficult to prescribe areas, but we must not lose sight of the fact that the provision of health centres will not exempt general practitioners from domiciliary services. Therefore it would be reasonable to expect them to be within reasonable reach of the area they serve. I think it would be most unfortunate if the impression went out that all doctors had to do was to serve a number of hours at a health centre, and then go home and forget all about their obligations. Domiciliary services are at least as important as the health centre. The doctor would have to be within access of his patients." (Col. 813.)

Personal Responsibility: Mr. BEVAN: "The doctors at the health centre will be able to make arrangements for emergency calls. But the doctors themselves have emphasized, and I agree with them, that continuity of treatment by the same doctor for the same patient is a very necessary condition; and we are not handing the patients over to a team of doctors at the health centre. That personal contact must be maintained. But we are embarking on this in an ambitious and experimental mood, and we shall have to feel our way for a considerable

time in the organization of the service. I regard the health centres as a very important part of the service indeed." (Col. 814.)

Decision of Disputes (Clause 47)

Promise.—Mr. BEVAN undertook to look into the desirability of making an amendment to provide that, in disputes between an individual and the Executive Council or between the Executive Council and the local health authority, an opportunity may be given for a hearing by a person appointed for the purpose by the Minister. (Col. 816.)

Refresher Courses (Clause 48)

Intention.—On the question of providing for refresher courses for optical, as well as medical and dental, practitioners, Mr. BEVAN said: "I think that the Amendment is unnecessary. As I understand it there is nothing inhibiting in the Bill which prevents appropriate arrangements being made for all health workers to be properly trained, and proper training means re-training and being kept up to date. It is not necessary to state this in the Bill. The Amendment would have the effect of making provision for refresher courses for eye-testing opticians in the temporary services, and I do not think that can be the intention. It is our purpose to go ahead with the permanent service as quickly as possible." (Col. 819.)

Mental Health Services

Certification of Institutions (Clause 49 (1))

Change.—The words "as private patients" have been omitted "because, in special instances, it may be required that the Minister shall arrange for the treatment in a certified institution of a patient who would normally be treated in a hospital vested in the Minister. Such a patient would not, and could not, be regarded as a private patient, and therefore we desire to omit these words." (Col. 827.)

Disqualification of Commissioners (Clause 49 (2))

Change.—Application of Section 24 of the Mental Deficiency Act to Commissioners as well as the Secretary and Inspectors.

Designation of Mental Hospitals (Clause 50)

Change.—The words "is or forms part of a hospital" have been inserted to enable "the Minister, as a temporary measure, to include in the designation of a mental hospital a small Poor Law institution in which only mental patients are accommodated, or the separate wards of such a Poor Law institution that are so used, and the result will be that, temporarily, the patients accommodated in such places will come under the care of the medical and nursing staff of the neighbouring mental hospital, and the hospital management committee responsible for their maintenance will be that of the mental hospital. The Poor Law authorities will, therefore, cease to have any statutory responsibilities or duties towards these people, but, temporarily, they will have to be accommodated there until there is adequate accommodation for them in a proper mental hospital." (Col. 828.)

Workhouse Mental Patients (Clause 50 (4))

Change.—An omission has been made to remove "the words which unnecessarily restrict the transfer of a mental patient from a workhouse to a mental hospital or institution for defectives in the particular regional area." Mr. KEY gave an assurance that the administrative freedom thus given would not be abused. (Col. 829.)

General

Appointed Day (Clause 53)

Intention.—The appointed day for the purposes of the Bill is to be April 1, 1948. (Col. 832.)

Grants to Local Health Authorities (Clause 53)

Promise.—Mr. KEY: "It is hoped to get the amending Bill with regard to the block grant system into operation by the time this Bill becomes operative from its appointed day. If that happens this Subsection will not be operative, but we want

it included, and we must have it in case of accidents—if, for instance, we do not get the necessary legislation bringing about the changes in the block grant. It is only for that purpose that we must retain it in the Bill." Mr. Key promised to see what could be done to lighten the burden on local authorities. (Col. 832.)

Payments to Regional Hospital Boards, etc. (Clause 54)

Intention.—Mr. KEY: "Our ideas on the way in which this service will be financed are these. First, that the hospital management committee itself will provide to the Regional Board for its area an estimate of its expected expenditure during the coming twelve months. . . . From the information which the Regional Board obtains from each of the hospital management committees for its area the Regional Board will know what sum of money is wanted for the carrying out of the service in its area. It will be able to negotiate with the hospital management committees. . . ."

"That will have to be submitted to the Minister and must be the subject of analysis, and it will be subject to approval by the Minister, because he must give careful consideration to that expenditure. He must decide whether or not, with the knowledge that the Department will have of the general hospital services of the country, a particular region is carrying out its functions in the way in which it should, and meeting the necessary expense for it. He must decide whether, on the contrary, in view of the expenses for the service as a whole, any particular region, for the time being, is exceeding what should be done at that particular time, if the service as a whole is to be adequately financed. But that expenditure having been approved, the Regional Board will have allocated to it its annual amount of money for the carrying out of the services; and the Regional Board will allocate to the hospital management committees their proportion of the regional sum for the purposes of running the institutions for which they are responsible.

"It is our desire that the Regional Boards and hospital management committees, so far as the expenditure of that money is concerned, shall have a considerable amount of latitude within the limits of the sum that has been approved." (Cols. 837-8.)

"If a management committee has a grievance, there is access to the Minister, because both are agents under the scheme." (Col. 840.)

Default Powers of Minister (Clause 57)

Change.—An amendment was accepted to provide that "except in the case of a local authority, the members of the defaulting body should be deemed forthwith to vacate their position, and the Minister shall appoint new people to carry the functions. While that is being done, some person shall be appointed for the carrying out of the functions in the interim." (Col. 849.)

Promise.—Mr. BEVAN promised to look into the wording of the later part of the amendment. (Col. 854.)

Acquisition of Land (Clause 58)

Change.—Amendments were made to make applicable to authorities under the Bill the powers of compulsory acquisition of land contained in the Acquisition of Land Act, 1946. (Col. 855.)

Research (Clause 58)

Intention.—Asked to give an assurance that "he has no desire for that complete monopolistic set-up with regard to the institutional treatment of those who are ill," Mr. BEVAN said: "I agree that in the field of medicine all kinds of experimental work go on. All kinds of modern forms of therapy are now being carried out by doctors whose predecessors cursed them heartily a generation or so ago. I would have thought, therefore, that it would be obvious that no Minister of Health with a health service worth defending would try to prevent the growth of institutional forms of treatment and other forms of therapy which might establish themselves, and I believe that anybody can go on experimenting without the fear that the Minister of Health will pounce summarily upon his buildings and apparatus. In fact, I can give that assurance, if the right hon. and learned Gentleman requires it. I think he agrees that the powers are necessary, but they will be exercised very rarely indeed." (Cols. 856-7.)

Gifts to Hospitals (Clause 59)

Promise.—On an amendment to include hospital management committees among the bodies which may accept gifts Mr. BEVAN said: "It seems to me, however, that it ought to be possible for the hospital management committee to take gifts, for if hospital management committees cannot take gifts it is unlikely the gifts will go to the Regional Board. It is too far away. People normally do not give gifts to a board; they give gifts to a hospital. Therefore, if we are to have gifts at all, they must go to the management committees. But I do hope that the committees are not going to start begging. I think that would be wholly undesirable—I mean, begging in the old way. It would be wholly undesirable in a State hospital service. I agree with the principle of the Amendment, and I hope that it will commend itself to my hon. Friends on reflection. But as we are going to make some Amendments to the scheme, on the lines suggested earlier, perhaps the right hon. and learned Gentleman will withdraw the actual Amendment, on the understanding that on the Report stage we shall include this, along with other alterations." (Col. 861.)

Termination of E.M.S. (Clause 59)

Promise.—Asked whether he had powers to ensure the financial stability of hospitals during the transitional period when the E.M.S. came to an end, Mr. BEVAN said: "Speaking without examining the matter properly, it appears that, at the moment, I have not got the powers. Powers to provide money under the Emergency Medical Service are restricted to certain purposes. However, I will have a look at the matter further, because I agree that a depletion of a hospital's finances may have a very serious effect upon it, and I will certainly see what interim action can be taken." (Col. 865.)

Power of Trustees (Clause 60)

Promise.—Mr. BEVAN promised "to find appropriate language" to include hospital management committees in the Clause. (Col. 867.)

Machinery for Deciding Remuneration (Clause 62)

Intention.—Replying to an amendment to exclude employees of local health authorities, Mr. BEVAN said: "We propose to use the existing machinery, which is quite adequate for the purpose, and where machinery does not exist among some sections it is proposed to call it into being." (Col. 874.)

Compensation or Alternative Employment (Clause 64)

Intention.—With reference to the exclusion of contributory scheme workers, Mr. BEVAN said that it would be impossible to pay compensation to persons indirectly affected by the scheme. "What the Minister of National Insurance and I will do, however, is to give a firm guarantee that we will do our utmost to absorb these people in a new service." (Col. 877.)

Eligibility for Compensation (Clause 64 (e))

Change.—The following has been inserted as a definition of the class of officers who will be eligible for compensation:

"subject to any prescribed exceptions or conditions, by the Minister or such local health authority or other local authority as may be prescribed, to persons who immediately before the appointed day—

(i) devoted the whole of their time to employment by the governing body of a voluntary hospital, a local authority, an insurance committee, or any such other body as may be prescribed, or to any combination of such employments;

(ii) were employed for at least part of their time for the purposes of any hospital transferred to the Minister by virtue of this Act or for the purposes of functions which cease, or are transferred from the employing authority or body, in consequence of this Act,

and who suffer loss of employment or loss or diminution of emoluments which is attributable to the passing of this Act." (Col. 885.)

Machinery for Arbitration (Clause 64)

Change.—Regulations will provide for the determination of questions arising under the regulations concerning compensation, "in order that it may be possible to provide machinery for arbitration." (Col. 887.)

Compensation for Hospital Officers (Clause 64)

Change.—Words have been inserted to deal with the case of officers employed by hospitals in areas of more than one region. This applies particularly in the case of the London County Council, where hospitals may cover more than one regional ward area." (Col. 888.)

Transfer of Functions (Clause 65)

Change.—Words have been inserted "to empower the Minister to make Regulations for the transfer of the property and liabilities of the Dental Benefit Council and the Ophthalmic Benefit Approved Committee." (Col. 888.)

Inquiries (Clause 66)

Promise.—Mr. BEVAN accepted the principle of an amendment to provide that the costs of an inquiry should not have to be borne by the local authorities. He promised to "insert more appropriate words at a later stage." (Col. 889.)

Charges for Services (Clause 68)

Change.—An amendment has been made "to enable local authorities to collect the necessary moneys in connexion with charges for certain services they have rendered. They have asked for this in this form. The Amendment enables regulations to be made for the recovery by local authorities as well as by regional boards for charges of appliances, medical accommodation, and so forth." (Col. 890.)

Exemption of Judges and Justices of the Peace from Disqualification (Clause 68)

Promise.—Mr. BEVAN said "he would try to find out for himself" why the paragraph is in the Bill. (Col. 891.)

Regulations and Orders (Clause 69)

Intention.—Invited to give an indication of his views in the matter of regulations and orders, Mr. BEVAN said: "It is true that Ministers are taking many more powers to issue Regulations and Orders than existed before. If hon. Members will go back to the National Health Insurance Act they will find that almost the whole of the Act was by Regulation and that there was very little in it all. It was entirely transformed by the issue of Regulations. I would point out that there is a Statutory Rules and Orders Standing Committee which examines the Regulations issued by Government Departments, and that therefore the House of Commons has more protection than before. With due modesty, I would point out that I was the inventor of that procedure. The attention of the House is directed to those matters where some question of principle is involved. . . . There are, of course, a number of Orders which do not come before the House in that way. The question arises as to what subjects are appropriate for that kind of instrument. I should have thought that the making of the regional authority was one of those. It is an executive act as to what particular area a region should cover. It is not a question of principle, but a question of convenience, sound organization, and administration. I should have thought that that was a subject which could have been done by Order." (Col. 892.)

"In order that the minds of hon. Members may be refreshed, those matters requiring affirmative Resolutions are also classified as regulations, but where the regulation needs to have an affirmative Resolution by the House before it becomes operative, that is stated in the text of the Bill. Where it is merely a regulation without any qualification, it means that it can be annulled by a Prayer—a negative Resolution of the House. Where it is an Order, it is an administrative act, and does not come before the House in either of those ways. There are some regulations which, in my view, ought to be done by affirmative Resolution. Those are where superannuation is affected, for example, and finance is involved. They have to be approved by the House before they come into operation. . . .

Where I have thought that those matters are of importance I have suggested, and put in the Bill, that Parliament should be asked; but adaptations of the scheme, modifications urgently required in the interests of the people concerned, in some instances might not be able to be done because of the congested character of the Parliamentary agenda, and we would find considerable difficulty. It can be said with considerable point that if they are urgent the Government must give time, but there will always be competition for urgency." (Cols. 895–6.)

"I am inclined, unless I receive very strong arguments to the contrary in particular cases, to stick to the plan as laid out in the Bill. I am not disposed to resist in every instance. Where there is a case that can be shown, it seems to me we might give way. At the moment, however, I cannot see where such a case can be made. Hon. Members should bear in mind that, while they insist that affirmative Resolutions are necessary, they are throwing into what will be an extremely complicated administrative job an added complexity and difficulty which would increase considerably the work of those concerned with the administration of the scheme. Therefore I hope that hon. Members will not press me too far." (Col. 897.)

Constitution of Regional Areas (Clause 69)

Promise.—Mr. BEVAN: "I will . . . see if it is possible to frame some words by which the constitution of the regional areas can be dealt with, not by affirmative but by negative Resolution. (Col. 906.) . . . I will do my very utmost to see that there is a form of words by which the regional areas themselves can be discussed in the House, if the House wishes to do so." (Col. 908.)

Central Health Services Council (Clause 69)

Change.—Words have been inserted "to make subject to a negative Resolution of Parliament any order of the Minister varying the constitution of the Central Health Services Council. It was felt that, as the words in the Bill stand, the Central Health Services Council would not have enough status unless any variation of its constitution could be challenged by Parliament." (Col. 911.)

Superannuation Benefits (Clause 72)

Change.—Provision is added for the transfer of liabilities, including the payment of superannuation allowances, of authorities which have been dissolved. (Cols. 912–13.)

Definition of Hospital (Clause 73)

Change.—The words "the reception and treatment of patients" have been substituted for "providing treatment," to make clear that "the hospital is a residential building for the reception of people for convalescent and rehabilitation treatment." (Col. 915.)

Definition of Illness (Clause 73)

Change.—Disability requiring dental treatment has been included in the definition of illness. (Cols. 915–16.)

Definition of Superannuation Benefits (Clause 73)

Change.—A definition has been inserted. (Col. 917.)

Definition of Specialist (Clause 73)

Intention.—During a discussion on the definition of illness Mr. BEVAN made the following statement: "I explained, when this matter was formerly under consideration, that I would take the advice of the profession as to what the definition of 'specialist' would be. At the moment I do not know what it is, and my ignorance is shared by the profession itself. The profession itself has not a definition of 'specialist' which is sufficiently precise to enable me to put it into the Bill. Furthermore, there will be, in some instances, general medical practitioners who, although they are only classified as 'general medical practitioners,' have shown, by special aptitude and experience, that they can be relied upon to give a particular form of treatment as well as a specialist who has academic qualifications in the subject. In some circumstances, therefore, we want to try to leave it to the advisory bodies themselves, operating through me and the Regional Boards, to define those particular general practitioners *ad hoc* as specialists for the

purposes of the administration. That is made all the more necessary by virtue of the fact that there is an inadequate supply of specialists with objective specialist qualifications. I think the right hon. Gentleman can take it from me that in this matter I shall move with the greatest possible caution in order to get the advice we need." (Cols. 919-20.)

New Clauses

Provision of Special Schools (New Clause)

Change.—A new Clause has been added to enable Regional Hospital Boards or Boards of Governors of teaching hospitals to arrange with a local education authority or voluntary organization for the use of hospital premises as a special school and for the maintenance of children where necessary. (Cols. 920-1.)

Stamp Duty (New Clause)

Change.—A Clause has been added to exempt from stamp duty documents given by or to Executive Councils. (Col. 923.)

Supply of Goods by Local Health Authorities (New Clause)

Change.—A Clause has been added to facilitate schemes for central purchase and distribution of stores and supplies. (Cols. 923-4.)

Industrial Health Service (New Clause)

Intention.—An amendment, which was withdrawn, required the Minister, within five years after the appointed day, to prepare a scheme for an Industrial Health Service. During the discussion Mr. BEVAN said: "It is perfectly true that there will have to be an Industrial Health Bill later on, but I think that hon. Members will find that, when this scheme has been in operation some time, the industrial health scheme will fall into line with infinitely more luminosity than appears at the moment. If we had put an industrial health service into this Bill we should soon find ourselves in frightful difficulties, and would soon need to have an amending Bill, because at the moment the relationship between industrial health and general health is not sufficiently clear; but it will occur, in course of time, that the health service under this Bill will assimilate, by its own administrative momentum, quite a considerable amount of what is described as industrial health services." (Col. 926.)

Patent Medicines (New Clause)

Intention.—A new Clause, which was withdrawn after discussion, sought provision for the appointment of an expert committee to prepare and maintain a list of medicines which are not recommended for prescribing by medical practitioners for use by the public, the purpose being "to remedy a situation whereby the new service is in competition with an uncontrolled health service." (Cols. 944-6.)

Mr. BEVAN said: "I sympathize with the purpose that lies behind this new Clause, but I want to tell hon. Members that this is much too wide a subject to tuck in at the end of a Committee stage. It has all kinds of repercussions; it is the kind of legislation which has to be very carefully considered before it is drawn up, and I would like hon. Members opposite to realize that the doctors themselves would say that the Clause, as at present drafted, is an interference with their right to prescribe. . . . I would say that whereas, in my opinion, the time has arrived, and indeed is long past, when the public of this country should be entitled to be protected against the ramp that is at present going on, nevertheless it is a subject with such wide repercussions that it must be dealt with in entirely separate legislation and not, as I have already said, introduced at the end of the Committee stage in a Bill of this sort." (Col. 949.)

Asked whether he regarded the problem as "something with which he hopes to make progress before long," Mr. BEVAN replied: "A legislative matter is not something for one Minister to deal with. All I can say is that I regard it as a matter of some urgency." (Col. 950.)

Grants to National Bodies (New Clause)

Intention.—In rejecting a new Clause to provide for grants to national bodies concerned with the improvement of the physical and mental health of the people, Mr. BEVAN replied he sympathized with a good deal of what had been said, but "I am advised that the words are unnecessary and that under the

Health Act, 1919, and, indeed, under Clause 1 of this Bill, I have already wider powers than would be conferred upon me by the proposed new Clause." (Col. 951.)

Schedules

Central Administrative Machinery (First Schedule)

Intention.—On an amendment to include the Chairman of the Dental Board in the Central Council Mr. BEVAN said: "I earnestly hope that in this Committee to-day there will be no auctioning of seats on this Council. . . . Doctors have exerted considerable force, but I think that the doctor is in rather a different position because he has an over-all responsibility for the health services, considered in their sum. A doctor covers other health services like radiology, pharmacy, and others that I could mention. Considering the doctor in the abstract, he is the person who, in himself, sums up all the various health services and, therefore, he has a different relationship to the health service as a whole.

"When we come to consider the practical work of this Central Council Advisory Committee we have got to think of it working more through subcommittees than working as a whole. It is a technical advisory body, and not an administrative body. When we come to the statutory advisory committees we have the really important people who are collecting the information, sifting it, analysing it, giving their experience and passing it on to the Central Council for them to consider it in its relationship to the health services as a whole, in order that they may be able to advise the Minister upon the wider repercussions of whatever report the committees make.

"I therefore submit that these people should be lay members. We want to bring into the Central Council the fresh air of lay approach. Otherwise we get far too much technical inbreeding. I think most of the doctors themselves would agree with that. The same reasoning will apply to the other boards throughout the service. It is necessary for us to have very strong lay representation in order that we may get an effective service." (Cols. 955-6.)

Hospital and Local Government Representatives (First Schedule)

Change.—The words "not being medical practitioners" have been inserted. (Col. 958.)

Expenses of Members of Central Council and Standing Committees (First Schedule)

Change.—Provision has been included for payments in respect of loss of remunerative time. Mr. BEVAN said: "It will be extremely difficult for many people of poor means to serve on some of these Regional Boards and some of the other institutions established under this Bill unless they are able to receive payment for loss of remunerative time. It would have been possible to have put in rather more precise language than this, except that there is no authority at present for the payment for loss of remunerative time to persons on local authorities in Britain. There is some provision for some local authorities in Scotland. I am setting up a committee of inquiry to advise me as to what and how local authorities should be authorized to make payment for loss of remunerative time and/or subsistence allowances, and the circumstances in which it should be done. I want to take power here in order to marry the two schemes, because we do not want two different conditions and standards of payment existing in the country as a whole. I think this is a provision with which the Committee will agree. It would be most unfortunate if a very large body of experienced people were prevented from participating in the administration of these important services merely on account of the fact that they were financially unable to do so." (Col. 959.)

Regional Hospital Board (Third Schedule)

Intention.—During discussion Mr. BEVAN said: "After the Boards have been set up and we have had experience, we must have modification. We shall certainly have to modify administratively." (Col. 972.)

Lay Representation on Regional Boards (Third Schedule)

Intention.—During discussion Mr. BEVAN said: "The hospitals' administration and the economy of the hospital system are not necessarily jobs which doctors could do best. On the

trary, doctors do not always reach the highest level of collective sagacity. Individually they are the most charming and lucid persons, but, because of their immersion in their profession, their collectivity is not the sum of their individual intelligence by any means. Therefore I could not agree more with the proposal that lay representation must be encouraged on these Regional Hospital Boards, although that also must depend on the richness of the material available in the particular area." (Cols. 972-3.)

Consultation with Hospital Bodies (Third Schedule)

Change.—An amendment has been made to ensure that there shall be "consultation, not with some sort of general body as at present provided in the Schedule, but for the consultation of the management committee of a particular voluntary hospital with a committee which had before been responsible for running the voluntary hospital, or, where there is a group of voluntary hospitals coming under a management committee, that there shall be consultation with individual hospital committees for the hospitals concerned in that group and not with some general body representing voluntary hospitals for the whole of the region." (Cols. 974-5.)

Co-option (Third Schedule)

Intention.—In rejecting an amendment providing for the co-option of persons to hospital management committees Mr. BEVAN said: "I do not think the principle [of co-option] is one we should encourage. The management committee are responsible to the Regional Board, and the Regional Board are responsible to Parliament, through the Minister. We do not want to have persons who in some sense are responsible to nobody. I would have thought that with the provision that subcommittees would be appointed for special work we have covered the practical necessities of the case." (Col. 976.)

Consultation with Boards of Governors (Third Schedule)

Intention.—On an amendment, which was withdrawn, requiring the Minister to consult with the Board of Governors in filling vacancies on the Board Mr. BEVAN said: "All I desire is that such consultation shall not be insisted upon. In practice, of course, there would be consultation." (Col. 990.)

Board of Teaching Hospital with More than One Hospital (Third Schedule)

Intention.—An amendment sought to provide that the committee for such a unit would be composed partly of members of the Board and partly of members of the medical staff. Mr. BEVAN replied: "Circumstances vary so much, but there may be circumstances in which an infectious diseases hospital is closely associated with the general hospital, and it may be desirable to have a separate house committee, or it may not. I think this is one of the things we should leave to be decided in the circumstances concerned. It is desirable that there should be a house committee where the building is substantial; but, where it is unsubstantial, obviously it is not necessary. I think a sort of empirical test is required here." (Col. 992.)

Admission of Press to Regional Board Meetings (Third Schedule)

Promise.—In rejecting an amendment specifically dealing with this matter, Mr. Bevan gave an assurance that the object would be achieved by the regulations he would make under Part IV (d) of the Schedule. (Col. 996.)

Functions of Health Committees (Fourth Schedule)

Change.—An amendment has been made "to enable the local authority to give to its health committee certain other functions than those which it has in connexion with child welfare, midwifery, lunacy, and mental deficiency—functions which it has under other Acts as well. We desire that it shall have the power to transfer all these functions to its health committee if it so desires." (Col. 998.)

Inspection of Minutes of Health Committees (Fourth Schedule)

Change.—An amendment has been made to apply "to the proceedings of the health committee a practice prevalent with the proceedings of education committees." (Col. 1002)

Constitution of Health Committees (Fourth Schedule)

Change.—An amendment has been made "to make the majority of its health committee consist not merely of public representatives of its own body but of public representatives of other local authorities within its area, and it will give the sum total of public representation to the combined bodies." (Cols. 1002-3.)

Deputies on Tribunal (Seventh Schedule)

Change.—An amendment has been made in paragraph 5 to correct a mistake. "The Schedule, as it is now drafted, suggests that the Minister may appoint the deputy chairman, whereas he would be appointed by the Lord Chancellor. It also implies that all the members are professional, whereas one will be lay." (Col. 1008.)

Persons of Unsound Mind and Mental Defectives (Ninth Schedule)

Change.—Mr. BEVAN explained the reason for the numerous amendments to this Schedule. "The extension of the existing lunacy machinery is an extremely complicated affair. We are not, as I said on the Second Reading, altering the lunacy code. All we are doing is decanting mental institutions and care into the whole service. That means extracting them from a whole series of enactments and services. It is one of the most complicated pieces of legislation we have had for many years. It was discovered that there were a number of loose ends, that there were some enactments, or parts of enactments, which had been overlooked, and this series of Amendments is necessary to put the matter right. I am glad that they were discovered during the Committee stage, otherwise we should have had to provide for them on the Report stage." (Col. 1009.)

Consequential Amendments and Repeals (Tenth Schedule)

Change.—Numerous amendments were made in this Schedule. (Cols. 1013-16.)

ANNUAL REPRESENTATIVE MEETING, 1946

ADDITIONAL RESOLUTIONS BY DIVISIONS AND BRANCHES NATIONAL HEALTH SERVICE

Motion by BELFAST: That this meeting is of opinion that hospital services should be planned on natural hospital areas centred on universities, and Regional Committees should be set up for the purpose of co-ordination, control remaining in the hands of the local people.

Motion by BELFAST: That this meeting is of opinion that Council should take steps to inform as large a section of the public and the profession as possible that the proposed National Health Service is neither an insurance scheme nor a free health service, but would be paid for by involuntary contribution or other form of taxation.

Motion by BELFAST: That in the opinion of this meeting (1) The personal doctor-patient relationship be preserved and the National Service founded on the family doctor ideal.

(2) That the boards of management of the voluntary hospitals shall be enabled and encouraged to preserve their independence as autonomous bodies within a co-ordinated Health Service.

(3) That the National Health Insurance Scheme should provide hospitalization grants assignable by the insured patients to the hospital or nursing of choice.

Motion by BELFAST: That the term "National Health Insurance" be deleted in the correspondence when referring to the present proposed scheme and that the term "National Health Service" be substituted.

Motion by ISLE OF WIGHT: 1. (a) That this meeting, being of the opinion that the National Health Service Bill is about to become law, desires that immediate representations be made to the Minister of Health on the conditions of service (within the terms of reference of the Bill as known) which would be acceptable to the profession; (b) that the matter is of such urgency as to demand priority of action over all other business.

2. (a) that the ruling principle in the working of the scheme be the interest of the patient and not that of the administration; (b) that the doctor be free to decide the treatment to be afforded to the patient, without interference or direction; (c) that the remuneration of the general practitioner should be directly related to the number

of patients on his list, special areas being dealt with in agreement with the profession. (A scheme is suggested in which remuneration would be determined by the number of patients, but that increases should be made based on number of years of service); (d) that units of mileage be reckoned in patient values at the rate of (say) 10 units of mileage (or difficulty of access) to 1 patient, in addition to the payment for the cost of the journeys; (e) that all income be free of professional expenses—e.g., cars, instruments, emergency drugs, telephones, rent, heating, lighting, upkeep of surgeries and waiting-rooms.

3. That the allowances for cars be computed by (a) a flat rate to cover depreciation, upkeep, insurance, road licence, driving licence, etc., running expenses to patients within 2 miles, and (b) a mileage basis to be calculated on a distance basis.

4. That leave be at the rate of 42 days per annum with locum tenens supplied by the Ministry.

5. That a retiring age (say 65 years) be set.

6. That an adequate pension be provided at the retiring age.

Motion by LEICESTERSHIRE AND RUTLAND: That this meeting recommends to the Council the desirability of circulating a referendum to each consultant and general practitioner when the time is deemed opportune. This referendum should seek to ascertain whether the individual is willing to accept or not to accept service under the terms of the new Health Service. In addition it should point out that should the individual's reply be to decline service then such refusal should not be effective unless at least 75% of the replies were against accepting service. This figure of 75% should apply to the area of each individual Branch, and also to the total number of Divisions or Branches of the Association.

Motion by TYNESIDE: That in the opinion of this meeting, the local medical committee referred to in clause 32(a) of the Bill should be elected and constituted on similar lines to the present panel committees—that is, one practitioner, one vote; nominations for all appointments to be approved by this committee.

Motion by GREENWICH AND DEPTFORD: That with reference to para. 117 of the Council's Report this meeting regrets that no reference is made to an alternative scheme for the treatment of patients in the event of the National Health Service Bill proving unacceptable to the B.M.A. and further suggests that a list of practitioners be compiled who would undertake to refuse service provided a sufficient number of practitioners give a similar undertaking.

HOSPITALS

"General Practitioner" Hospitals

Motion by BELFAST: That this meeting urges on Council the importance of the preservation and the development of the small general hospital, staffed by general practitioners, and recommends Council to press for the development of such hospitals within the National Scheme, it being clearly understood that it is essential at the same time to maintain the closest possible co-operation between general practitioners and those in consultant and specialist practices.

Chronic Sick

Motion by BELFAST: That with reference to para. 21 of the Council's Report, this meeting wholeheartedly supports Council in its recommendations for the care of the chronic sick and elderly, the infirm and incurable, and emphasizes the need for the periodic review of the diagnosis of cases in the light of advancing scientific knowledge.

GENERAL PRACTICE

Fees for Life Insurance Examinations

Amendment by BRIGHTON: That "one guinea" be substituted for "10s. 6d." in the last line but one.

NATIONAL HEALTH INSURANCE

Remuneration of Insurance Practitioners

Motion by LANARKSHIRE: That failing an immediate and adequate upward revision of the N.H.I. capitation rate—made retrospective to Jan. 1, 1946—the Insurance Acts Committee be advised to consider taking steps to terminate the present agreement with the Minister.

Motion by NEWCASTLE-UPON-TYNE: That in view of the fact that the Government has in the past shelved repeated requests for a higher capitation fee on the grounds that the Spens Committee was investigating the problem, and in view of the increasing cost of living, the Government should be told that it is now a matter of extreme urgency.

Regional Medical Service

Amendment by BRIGHTON: That this meeting is not satisfied with the attitude of the Minister and instructs Council to pursue the matter further.

Amendment by GREENWICH AND DEPTFORD: That this meeting views with concern the attitude adopted by the Minister of Health with regard to the reference of patients to specialists as being a definite interference with the relationship between doctor and patient, and demands that the Council take a firm stand against the Ministry over what they consider an encroachment of individual freedom.

SPECIAL PRACTICE

Consultants and Specialists and a National Health Service

Amendment by WORCESTER AND BROMSGROVE: That the following words be added to subsection iv: "but in the case of ambulant or movable patients there should be complete freedom of choice of consultant."

Access to Ancillary Departments of Hospitals

Amendment by GREENWICH AND DEPTFORD: That this meeting does not consider the "open door" policy is a wise or safe one in that the increasing flood of work it would bring to the ancillary departments would tend to lead to a situation where opinions would be given by technicians.

Post-mortem Facilities

Amendment by EAST YORKSHIRE: That this meeting does not agree that the decision as to who is a competent medical practitioner to perform post mortems should rest with the coroner.

PUBLIC HEALTH

Doctors employed Part-time by Local Authorities

Amendment by BRIGHTON: That this meeting expresses dissatisfaction at the result of the Council's deliberations, as the scale of salaries is not high enough to be in keeping with the present times, for whole time or part time.

Amendment by EAST YORKSHIRE: That this meeting regrets the continued demonstration of the chaotic position of scales of remuneration for practitioners on an item of service basis as exemplified in the Report of Council, 1945-6.

National Maternity Service

Amendment by GREENWICH AND DEPTFORD: That this meeting is of the opinion that for the recognition of the purpose of the future health service any general practitioner who desires to undertake obstetrics shall undertake to remain efficient in midwifery.

ORGANIZATION

Regional Organization

Motion by NEWCASTLE-UPON-TYNE: That in the opinion of this meeting the headquarters of the North-Eastern Regional Secretary should be in Newcastle-upon-Tyne.

OTHER MOTIONS OF DIVISIONS AND BRANCHES

Refresher Courses

Motion by BELFAST: That this meeting is of opinion that refresher courses should be made available for general practitioners at recognized teaching hospitals, and they should be facilitated and encouraged to attend them.

Rationing

Motion by BELFAST: That this meeting protests against any proposal to make rationing a permanent feature of post-war British policy and will protest against any form of discriminative rationing for political party purposes.

Medical Education

Motion by EAST YORKSHIRE: That this meeting suggests to the appropriate authorities that, in order to expedite the qualification of medical practitioners, the method adopted during the late war of shortening holidays and inserting an extra term in the academic year be continued.

RETURN TO PRACTICE

The Central Medical War Committee announces that the following have resumed civilian practice: Mr. Richard Battle, F.R.C.S., at Gorslands, Horsell Common, Woking, Surrey, and at 148, Harley Street, W.1 (Wolbeck 1207); Dr. N. S. Plummer, F.R.C.P., at 49, Harley Street, W.1; Mr. F. J. Rutter, F.R.C.S.Ed., at 3, Barnfield Crescent, Exeter; Mr. Reginald S. Strang, F.R.C.S., at 3, Westbourne Road, Edgbaston, Birmingham, 13; Dr. C. C. Ungley, F.R.C.P., at 13, Portland Terrace, Newcastle-upon-Tyne, 2.

Correspondence

Recognition of Honorary Workers

SIR,—The next few years promise to be the most momentous in the history of the medical services of this country. Many GPs, general practitioners and specialists alike, have worked hard on behalf of their colleagues in the past few years in a completely voluntary capacity either in their local Divisions or in the B.M.A. or on the central committees, often putting themselves out of pocket by their efforts. Many more have served their brethren just as industriously in the years to come without thought of reward. Is it not time we recognized the good work they are doing on our behalf by conferring some honour upon them? I am given to understand that resolutions of thanks passed in committee are the present method of acknowledging their work.

I wish to propose that the title of "Fellow of the British Medical Association" be conferred on those of our colleagues who have given continuous and exacting voluntary service on behalf of their colleagues over a number of years, or to any member whose work gives some outstanding contribution to the work of the Association. I suggest that the Divisions, Branches, and central committees be examined for those men worthy of the honour and that their names and deeds be submitted to the Council for consideration. Other methods of honouring such worthy members, for instance the granting of membership or the presentation of medallions, may appeal more to other members.

If some such scheme receives the support of the Association certain benefits should be available to those so honoured—such as the provision of an annual dinner, invitations to the Representative Meetings, and *ex-officio* membership of certain or all committees in their Branch or Division. Let us recognize those who selflessly work on our behalf yet so frequently receive little support in their labours,—I am, etc.,

London Hospital, E.1.

W. R. WELPLY.

Permanent Appointments

SIR,—In the *Supplement* of March 23, "Military Psychiatrist" suggests that the establishment of permanent appointments should be deferred for a longer period. Your reply states that the Council of the B.M.A. has reduced the period from four months to two. This reduction has been resented by medical officers in the Pacific, most of whom, like myself, do not receive the *Journal* for three months after the date of publication—i.e., one month after the closing date for applications. Decisions such as this and the protracted demobilization of specialists are fast creating an outlook of distrust which resembles that seen in men serving in Burma in the early days of the war. The period for appointments should be re-extended to four months to let doctors in these parts feel that they are at least able to apply.

Unlike your correspondent Ian G. Wickes (in the same issue) I am not in a plane flying home for demobilization and must therefore sign myself,

"MEDICAL SPECIALIST."

Release of Specialists

SIR,—I have noticed, with some distaste, letters recently published in the *Supplement* from specialist medical officers complaining of tardy demobilization, being in age and service groups around 40. From the age groups of these officers one suspects that they were comparatively late in joining the Forces, possibly in many cases acquiring specialist qualifications at the time when many others were experiencing the rigours or weariness of war.

Medical specialist officers have at least the advantage of doing congenial work in their own branch of medicine—a privilege often denied to the general duty medical officer. There are, I am sure, large numbers of ex-Service medical officers, like myself, who were general practitioners, and who did six years of general duties, and are now attempting to rehabilitate themselves, at some inconvenience and economic loss. I have no doubt that they also look upon the somewhat whining complaints I have mentioned with equal distaste.—I am, etc.,

"EX-NAVAL M.O."

Protection of Practices

SIR,—The survey of the working of protection of practices schemes (Appendix to Supplementary Report of Council, *Supplement*, June 22, p. 182) leaves several grave omissions, which I am sure many of the serving members will agree. The one factor which militated against the successful working of the plan was the good will and honour lacking in the remaining profession. I fail to understand how proud we are to feel with the return of £36 per year (average figure) for our private patients. How are we to feel proud of anything up to a 61% loss in our insured persons? The difference between insured and private returns shows that had not lists been closed we would have been left with nothing. Praise is due to local medical war committees and is merited—they tried hard with a disinterested profession.—I am, etc.,

Romford.

G. A. K. STEEN.

Domestic Help for Doctors' Wives

SIR,—The feeling letter of Dr. M. L. Farmer (*Supplement*, July 6, p. 3) gives but another instance of the Ministry's woeful ignorance and wilful neglect over any matter concerning the G.P.—not forgetting his poor wretch of a wife. But what is writing to the *B.M.J.* going to achieve? Even as I write, every suggested amendment to the National Health Bill is negatived or withdrawn peremptorily. Who, then, can make the Ministry recognize the debt it owes to the G.P.'s wife, and, having secured recognition, who is to produce "a scheme" and who is to implement it to relieve our wives, and how and when? If the Ministry can filch our practices, our bodies, and our houses, it is not likely to stop short at our wives. And meantime? Does the Ministry care if our door-bells go unanswered? Does it care one jot if a telephone operator wearily informs an urgent caller, "Surrey, no replay"? And who cares if our wives are in a queue? There may be some Ministries unaware of the existence of queues whether of doctors' or dockers' wives, as was shown by statements recently in the House when bread-rationing was being discussed (for want of a better word).

But poor Dr. and Mrs. Farmer, together with many other doctors and their wives, must prepare themselves for worse to come: when they reach the advanced "lonely sixties," when their expenditure of much love, labour, and money on their children is a thing of the past, when perhaps their grandchildren are ill but denied visits from their grandparents because of domestic, professional, or other State-sent burdens, when their own health and strength decline necessitating frequent days or weeks in bed, when hard winters abound, when earning capacity is proportional to physical weakness and exhaustion, when whole years go by without a possible break or holiday, when they know they will be forbidden to sell practice or house and so hope for a well-earned retirement and rest from it all—when all these things come, as they have come to some of us, then, and not till then, may the Dictatorship shape a brave new world for others than youth. Wild plans will sprout to attract doctors to become G.P.s, and that will be a much more difficult problem than attracting recruits to the profession.

Those of us who married nearly forty years ago in the wicked Victorian era had love-nests for homes; even as beginners we could afford a maid; as years went by and the family grew we could have maids (in the plural), gardeners, and perhaps chauffeurs, and certainly casual labour enough. Wives lived a civilized life enjoying housewifery and motherhood to the full. The modern so-called labour-saving house is a snare and saves labour only for the builder. The doctor's house, as such, was never conceived. Did we in those days dream even for one moment that we should see our wives as drudges and ourselves as serfs? The pity of it all is that we can afford domestic help; but are we to condone the policy and wage-demand of the labour exchanges, who have not the slightest idea of the requirements of a professional house, in employing prostitutes, thieves, drunkards, and lesbians?

No, Sir. My *nunc dimittis* is soon to be sung and perhaps it will be as thankful as that of the pious Simeon, though for a very different reason; I think I shall be glad, when the time comes, to be out of a world so thoroughly marred by mankind and his machinations.—I am, etc.,

Orpington.

B. RICHARDSON BILLINGS.

H.M. Forces Appointments

ROYAL AIR FORCE

Air Cdre. (Temp. Air Vice-Mshl.) A. F. Rook, C.B., O.B.E., K.H.P., to be Air Vice-Mshl.

To be Fl. Lieuts. (Permanent): D. C. Bodenham, H. L. Jenkins, and J. Park.

To be Fl. Lieuts.: E. H. Lamb, J. K. F. Mason, and S. Paul.

ROYAL AIR FORCE VOLUNTEER RESERVE

Fl. Lieut. T. Hepburn has relinquished his commission on account of medical unfitness for Air Force service, retaining the rank of Squad. Ldr.

R. V. Payne to be Squad. Ldr. (Emergency).

Fl. Lieut. G. Ashforth has resigned his commission, retaining the rank of Squad. Ldr.

Fl. Lieut. A. R. V. Moynagh has relinquished his commission on account of medical unfitness for Air Force service, retaining his rank.

To be Fl. Lieuts. (Emergency): E. M. Edwards, D. G. Howell, A. K. Monro, J. A. Pugh, J. A. Taylor, G. Watkinson, and M. A. Floyer.

To be Flying Officers (Emergency): N. D. Ashe, G. F. Bacon, G. L. Bickler, J. G. Coxon, W. J. A. Dobson, L. G. Duff, J. Fraser, W. E. Hassan, J. F. Hudson, P. K. S. Joynson, C. H. Kinder, W. R. Lee, K. E. McIver, I. Mackenzie, R. W. P. Mellish, D. O'Keefe, A. S. Osier, I. M. Perkins, P. Seltzer, J. G. Shirreffs, H. Shooman, D. F. Street, W. C. Taylor, C. C. Vidot, R. V. Walley, L. R. Whittaker, R. A. Wilkinson, D. G. Wilson, W. E. J. Wilson, N. F. W. Brueton, J. Barr, J. S. Caldwell, K. D. Cochran, N. N. Davies, E. F. Ducat, R. F. Ewing, K. J. R. Ford, J. D. Galletly, G. E. Griffiths, F. Latham, P. S. London, P. R. Montgomery, J. Y. Moore, G. W. Morrison, J. A. B. Mounsey, W. D. Nicoll, R. C. McGregor, C. B. McKerrrow, J. McMillan, A. C. F. Ogilvie, J. O. Robinson, P. F. Scott, P. H. S. Silver, D. L. C. Thomas, M. Tobias, J. C. L. Wade, R. W. Wilkinson, C. D. Wilson-Sharp, and D. Wimbome.

INDIAN MEDICAL SERVICE

Capt. A. C. S. Mann has retired.

Association Notices

Sir Charles Hastings Clinical Prize

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of fifty guineas, is again open for competition. The following are the regulations governing the award:

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of fifty guineas.

2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.

4. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1946. The prize will be awarded at the Annual General Meeting of the Association to be held in 1947.

5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.

6. If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

7. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto, and enclosing the candidate's name and address.

8. The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal*, or for presentation to the appropriate Section of the Annual Meeting of the Association.

9. Inquiries relative to the prize should be addressed to the Secretary.

GROUP OF ANAESTHETISTS

Notice is hereby given of the formation by the Council of a Group of Anaesthetists, which shall be composed of all those members of the Association who are engaged predominantly in the practice of anaesthetics. Members of the Association who claim to conform to this definition, including those serving with H.M. Forces, are requested to complete and return the appended form to the Secretary, B.M.A. House, Tavistock Square, W.C.1. The first general meeting of the Group will be held at a date to be subsequently announced in the *Supplement*.

June 22, 1946.

CHARLES HILL,
Secretary.

BRITISH MEDICAL ASSOCIATION

GROUP OF ANAESTHETISTS

FORM OF APPLICATION FOR MEMBERSHIP

To the Secretary,
British Medical Association,
B.M.A. House, Tavistock Square,
London, W.C.1.

I wish to apply for membership of the Group of Anaesthetists. I am a member of the Association and am engaged predominantly in the practice of anaesthetics.

DIARY OF SOCIETIES AND LECTURES

MACKENZIE INDUSTRIAL HEALTH LECTURE.—At B.M.A. House, Tavistock Square, W.C., Wed., 5.45 p.m. Dr. Donald Hunter: Academic Aspects of Industrial Medicine. (Amended date.)

APPOINTMENTS

ROYAL LIVERPOOL UNITED HOSPITAL. Honorary Appointments.—At Royal Southern Hospital Branch: Radiologist, R. E. Roberts, M.D., F.R.C.P., F.F.R.; Assistant Physicians, G. Sanderson, M.D., R. R. Hughes, M.D.; Assistant Surgeons, R. W. Doyle, F.R.C.S., M. J. Bennett-Jones, Ch.M., F.R.C.S. At Liverpool Royal Infirmary Branch: Assistant Physicians, E. T. Baker-Bates, M.D., W. S. Sutton, M.B., M.R.C.P.; Assistant Surgeons, M. Silverstone, Ch.M., F.R.C.S., A. C. Brewer, F.R.C.S.; Assistant Orthopaedic Surgeon, R. Roal, F.R.C.S.; Assistant Gynaecological and Obstetrical Surgeon, Prof. T. N. A. Jeffcoat, M.D., Liverpool, F.R.C.S.Ed., F.R.C.O.G. At David Lewis Northern Hospital Branch: Assistant Physicians, C. A. Clarke, M.D., M.R.C.P., A. Thetwall Jones, M.D., M.R.C.P.; Assistant Surgeons, G. Stafford Mayer, F.R.C.S., W. R. Hunter, M.S., F.R.C.S.; Assistant Orthopaedic Surgeon, G. E. Thomas, M.Ch.Orth., F.R.C.S.Ed. At Liverpool Stanley Hospital Branch: Assistant Physician, R. M. Evans, M.B., B.Chir.; Assistant Surgeon, F. I. Evans, F.R.C.S.; Assistant Orthopaedic Surgeon, P. B. Moroney, M.Ch.Orth., F.R.C.S.; Assistant Gynaecological and Obstetrical Surgeon, Mary H. Maycur, M.D., F.R.C.S. At Department of Plastic Surgery: Assistant Surgeon in Charge, R. P. Osborne, F.R.C.S.

WOLVERHAMPTON: ROYAL HOSPITAL.—The following appointments to the honorary medical staff are announced: Physician: J. V. S. A. Davies, B.M., M.R.C.P. Paediatrician: H. W. Evertley Jones, M.B., M.R.C.P. Dermatologist: D. E. Oakley, M.B., B.Chir. Surgeons: R. L. Benison, F.R.C.S., and W. R. S. Hutchinson, F.R.C.S. Assistant Orthopaedic Surgeon and Fracture Officer: N. Heath, F.R.C.S.Ed. Anaesthetists: D. Masters Brown, M.B., Ch.B., G. W. Campbell, L.R.C.P.&S.Ed., and J. F. Rickards, M.B., Ch.B.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BELL.—On July 10, 1946, at 190, High Road, Loughton, Essex, to Susan (née Neill), wife of Dr. I. Montecath Bell, a daughter.

HARDIE.—On July 13, 1946, at Malvern, to Laurie, wife of A. W. Hardie, M.B., D.A., a daughter.

POWELL.—On July 3, 1946, at Clarence House, Rhyl, to Joan (née McAuliffe), wife of Dr. C. E. Powell—Richard, a brother for Christopher and Fiona.

MARRIAGE

STEVENS—RAWLINGS.—On July 2, 1946, at Caxton Hall, Licul. Col. A. V. Stevens, O.B.E., M.C., R.A.M.C., to Hilda Suzanne Rawlings.

DEATHS

BUCK.—On June 17, 1946, at "Havelock House," 9, Havelock Road, Lucknow, Eldred Theodore Buck, L.R.C.P.Ed., L.R.C.S.Ed., L.R.F.P.&S.Glas., aged 46.

MACKAY.—On July 4, 1946, at Glenora, Beaulieu, Roderick Mackay, M.C., M.D., beloved husband of Rita Nairne.

RUSHION.—On July 3, 1946, Susan Jane, aged 9 days, infant daughter of Joyce (née Newman) and Dr. E. P. K. Rushion, Colonial Medical Service.

K. D. KEELE, M.D.

Lieut.-Col., R.A.M.C.; Officer in Charge, Sprue Research Team, G.H.Q. (India)

The importance of sprue in India during 1943-5 is reflected in the fact that of 8,846 medical cases evacuated during that period 1,073 had sprue. The unusual opportunity of observing large numbers of cases early in the disease has provided the clinical material for this paper, which describes the development of the syndrome in two series of patients. The first 600 cases described previously† were studied under limiting circumstances. Few laboratory facilities were available. They will be referred to as A600. The second series of 80 cases have had fuller clinical and laboratory investigation. They will be referred to as B80.

Symptomatology: The Sprue Cycle

The symptoms of sprue are legion. A study of the early symptomatology revealed in 85% of cases the grouping of symptoms into two phases shown in Fig. 1, which is the chart

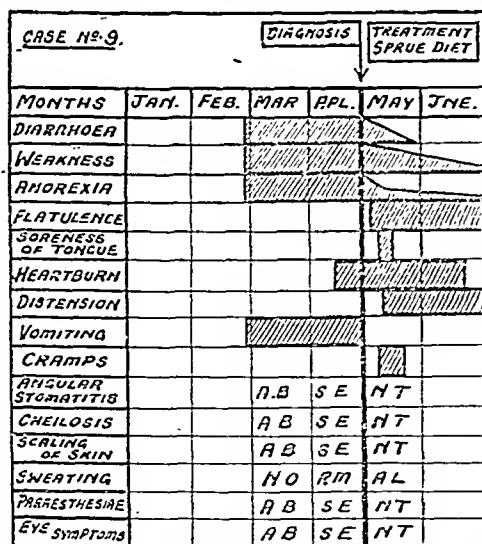

Fig. 1.—Diagram of the typical clinical picture in a case of acute sprue (mild).

of Case 9 of series B80. Symptoms of onset consist of anorexia, diarrhoea, vomiting, weakness, and loss of weight. Diarrhoea is usually, but not always, first; the other symptoms follow quickly, forming a clear symptom-complex which persists for a few weeks before further symptoms develop. These consist of glossitis, cheilosis, abdominal distension, and

scaling of the skin. At this time flatulence and heartburn increase and the symptoms of onset decrease or disappear; appetite returns to normal or to voracity, diarrhoea declines or changes to constipation, and weight loss ceases, often turning to weight gain.

In untreated cases this remission of diarrhoea and return of appetite results in overeating, which leads to return of diarrhoea, etc. With such relapse glossitis and distension decrease, but weight drops rapidly. This cycle may continue with progressive loss of weight and development of malnutrition.

The symptoms of onset and relapse are similar. The second group of symptoms—glossitis, distension, etc.—coincide with improvement in the general condition of the patient—e.g., return of appetite, gain of weight—and so have been grouped as symptoms of remission.

Fig. 2 shows the change of incidence of symptoms within two weeks of diagnosis of steatorrhoea and beginning of sprue

SYMPTOM	INCIDENCE OF SYMPTOM BEFORE DIAGNOSIS %	INCIDENCE OF SYMPTOM AFTER DIAGNOSIS %	CHANGE IN INCIDENCE %
DIARRHOEA	99	69	- 30
DISTURBANCE OF APPETITE	91	79	- 12
VOMITING	44	38	- 6
CRAMPS	14	15	+ 1
WEAKNESS	94	98	+ 4
HEARTBURN	60	65	+ 5
ANGULAR STOMATITIS	9	18	+ 9
CHEILOSIS	5	24	+ 19
SCALING OF SKIN	9	31	+ 22
FLATULENCE	73	96	+ 23
SORENESS OF TONGUE	61	90	+ 29
DISTENSION	60	95	+ 35

Fig. 2.—Showing change in incidence of symptoms after diagnosis and beginning of treatment in 80 cases of sprue.

diet. From this it will be seen that the symptoms of onset or relapse decreased rapidly in most cases in hospital, but those grouped as symptoms of remission increased in incidence. At first we failed to understand why patients should develop symptoms on sprue diet, but on observing relapses occurring under our own care it was noticed that the sequence diarrhoea, anorexia, loss of weight was often followed by sore tongue and distension on cessation of the diarrhoea, with improvement of appetite and gain of weight. Such a miniature cycle might be complete in a week in hospital. On a larger scale this was happening in cases admitted to hospital in persistent relapse, the symptoms changing to those of remission on treatment.

* Abridged excerpt from a report to G.H.Q.(I.).

† Keele, K. D., and Bound, J. P., *British Medical Journal*, 1946, 1, 77.

Symptoms of Onset or Relapse

Anorexia.—Starting usually after diarrhoea, this symptom may be pronounced. Weakness accompanies it. One of our cases had been for months diagnosed as anorexia nervosa. This patient responded to sprue therapy.

Vomiting.—Common in these cases. The symptom was often produced by men forcing down food in spite of anorexia. In severe relapse vomiting dangerously contributes to dehydration.

Diarrhoea.—This is almost constantly the mode of onset; pallor of stools appears after a variable interval. Stools may be frequent—15 to 20 a day. This, and response to sulphaguanidine, often lead to a diagnosis of "clinical dysentery." In remission the stools are always firm.

Asthenia.—A constant and marked symptom often occurring early. It is not accompanied by the symptoms of effort syndrome.

Loss of Weight.—Change of weight in normal men in India is about $\pm 10\%$. On admission to hospital many sprue cases had lost 25% of their English weight. Loss is very rapid in acute cases with dehydration.

Transition from Relapse to Remission

In the majority of patients admitted diet therapy produced the change of symptoms from relapse to remission (63% of cases treated dietetically alone). In some transition is slow and symptoms of relapse persist and vary, those of remission also appearing—e.g., diarrhoea alternates with constipation, glossitis comes and goes, and weight is not gained. Such static cases are turned into full remission with parenteral liver therapy, on which, after one week, the signs of relapse disappear, while distension increases, appetite returns, and weight is gained. When remission is induced by liver therapy, glossitis is always slight—much less than with remission on diet alone.

Symptoms of Remission

Diminution of the symptoms of the relapse phase is constant in remission. Symptoms that appear or are accentuated are:

Glossitis, Cheilosis, and Angular Stomatitis.—Glossitis has been present in over 90% of our cases. But it is not an early symptom. Many cases of steatorrhoea, on treatment, produced the necessary evidence to change that diagnosis to sprue. The average duration of diarrhoea before glossitis was three months. Glossitis appears at a period when signs of relapse are decreasing; it lasts about two weeks in a case treated by diet, during which time appetite improves, distension increases, and stools firm, pale, and bulky. After two to three weeks glossitis appears without any alteration in therapy—not to return less the patient relapses, when again it appears at transition from relapse to remission. Diets assessed at the time of onset of diarrhoea and the glossitis have not been deficient in vitamins of the B group. The appearance of the tongue has been frequently described. Emphasis should be given to the transient nature of the changes in early sprue. Improvement from a painful, fiery-red tongue to normal has often occurred in a few days. True depapillation is not present early. Angular stomatitis and cheilosis were less common, but they, too, markedly increased their incidence after admission to hospital.

Abdominal Distension.—At onset and during relapse abdominal distension is usually absent. This is particularly noticeable in acute severe cases. There is a remarkable increase of distension with response to treatment, coincident with the cessation of diarrhoea and vomiting. In this context it is a welcome sign. Distension persists through remission with steatorrhoea. Though flatulence increases with the distension, barium meals did not show this to be its cause.

Skin Changes.—Scaling of the skin with loss of hair increases during remission. This lasts about one month and subsides with continued satisfactory progress. Scaling is general, the size of scale varying from fine, branny desquamation to coarse ichthyotic plaques.

Signs of Vitamin Deficiency

In series A600, glossitis, angular stomatitis, and scaling of skin were often present. Out of 20 cases with scaling of the skin 19 showed no evidence of deficiency in dark-adaptation, rendering vitamin A deficiency doubtful. All these signs were

found to clear without specific vitamin therapy. The syndromes suggestive of deficiency of vitamins D and K, thiamine, or ascorbic acid were not seen.

In the series B80 it has been noticed that glossitis, angular stomatitis, and scaling of the skin increase in degree or appear for the first time in hospital on ordinary or sprue diets of high-protein low-fat type. Such diets have been adequate in nicotinic acid and riboflavin content.

In our wards, on an investigation diet designed to contain nicotinic acid 5–10 mg./diem and riboflavin 3 mg./diem, cases B53 and B66 developed marked exacerbation of glossitis, which cleared in 14 and 10 days respectively without any alteration of the diet; and in several instances patients admitted with glossitis have lost it on this diet without other treatment. These and other observations have not supported our expectations of relating the glossitis of sprue to simple nicotinic acid or riboflavin deficiency. In remission with parenteral liver therapy, however, glossitis is minimal or absent.

Nine cases of steatorrhoea of short duration with loss of weight responded to sprue diet therapy without glossitis. Thus early in this steatorrhoeic syndrome remission may occur without development of these so-called deficiency symptoms. Larval sprue (glossitis without steatorrhoea) was seen in only 7.5% of series B80. Such cases become rarer the more persistently steatorrhoea is looked for.

Barium Meal Skiagrams

The results of barium meal examination in 9 cases are summarized in the accompanying table. All patients were screened and filmed standing; films were taken using 0.12

Summary of Barium Meal Findings in Nine Cases of Sprue

Case	Weight Change	Stomach Emptied by	Mucosal Pattern	Region of Gut reached in			Marker Time (hours)
				1 hour	3 hours	6 hours	
1	—	6 hours	Bolus ++	Caecum	Descending colon	Sigmoid colon	13
2	++	6 "	Normal	Ileum	Caecum	Ascending colon	41
3	0	3 "	Bolus +	"	Ileum	"	8
4	0	3 "	"	"	"	Hepatic flexure	31
5	0	3 "	Bolus slight	"	"	Ascending colon	—
6	+	1 hour	Normal	"	Caecum	"	47
7	+	1 "	"	"	Ileum	Splenic flexure	56
8	++	6 hours	"	"	Splenic flexure	"	22
9	+	6 "	"	Hepatic flexure	"	Sigmoid colon	24

second exposure with 80–85 kV at 15 minutes, 30 minutes, 1 hour, 3 hours, 6 hours, and 24 hours following 4 oz. (113 g.) of barium sulphate in watery suspension, free of fat, and an iron marker of ferrous sulphate $7\frac{1}{2}$ gr. (0.5 g.), in capsule, at the start.

(1) The stomach-emptying time was variable—from 1 to 6 hours—and was not correlated with relapse and remission phase.

(2) The mucosal pattern could not be investigated by special contrast methods; gross changes only were noted.

FIG. 3.—Appearing of barium meal at 30 minutes in Case 1. A, In relapse. B, After one month of parenteral liver therapy, in remission.

Only one case was examined in severe relapse: with diarrhoea and loss of weight of over 40 lb. (18 kg.). In him the barium lumped into large masses in the jejunal region. Though these masses were firm and appeared static the marker was passed in 13 hours. This patient was re-examined one month later, in remission, having gained 20 lb. (9 kg.) on sprue diet and parenteral liver therapy. The intestinal pattern is shown in Fig. 3.

occurred motility decreased, markers being passed in about 24 hours in all such cases.

Anaemia in Sprue

Investigations were done on venous blood drawn without stasis, using Wintrobe's mixture as anticoagulant. Haemoglobin was estimated by Sahli's method: 15 g. % was taken

Fig. 4.—Typical blood picture in four cases of acute sprue. Hb in g. %; weight in pounds; RBC in millions/c.mm.; MCH (mean corpuscular haemoglobin) in γ ; MCV (mean corpuscular volume) in c. μ ; — Liver (T.C.F) 10 ml. for 4 days, then 4 ml. daily, I.M.

The change from the earlier appearance corresponds to that from relapse to remission. Cases 2, 3, and 4 were static; they showed less marked bolus formation. All four cases in remission showed apparently normal mucosal patterns.

(3) *Motility* was grossly variable, both through the whole gut and through various parts of it. But, in general, as remission

as normal. Erythrocytes were counted in a Neubauer's chamber, blood being diluted with Hayem's fluid in a Hawksley pipette. Packed-cell volumes were estimated, using cut-down Westergren tubes (Wintrobe's tubes were not available). Reticulocytes were counted by the Osgood-Wilhelm technique.

The degree of anaemia is not usually severe in early cases. In series A600 only 24% of cases had haemoglobin below 12 g. %. The blood changes were followed in several cases of series B80 (Fig. 4, which illustrates four representative types, with corresponding weight curves). Case 1 shows the response on diet therapy alone. Case 2 had very severe acute sprue (loss of weight 71 lb. (32.2 kg.), dehydration gross), which responded to parenteral liver therapy. Case 3 shows relapse on diet therapy with later response to parenteral liver therapy. Case 4 was a severe acute sprue which failed to respond to diet and liver but responded to transfusion.

In series B80 the initial blood counts showed: (a) macrocytic anaemia (26%); (b) normal haemoglobin and red blood cell count, but macrocytosis (30%); (c) normal blood counts (35%); (d) hypochromic anaemia (9%). In remission the change has always been: from macrocytic anaemia to normal haemoglobin with macrocytosis; to normal counts with complete remission.

Hypochromic anaemia has been uncommon (9%); all were cases of mild sprue, responding to diet therapy alone. Helminthiasis was found in 3 cases only—in one, ascariasis; in one, *Strongyloides stercoralis*; and in one, *Ancylostoma duodenale*.

The following summarizes the red blood cell changes found:

At the onset of sprue the blood changes are slight, even with profound loss of weight. Dehydration may mask some changes. When anaemia develops it is macrocytic from the start in most cases. With remission the macrocytosis persists, the haemoglobin rising slowly. Reticulocytosis is not marked: normoblasts do not appear. As the patient reaches normal weight, and not before, the blood picture returns to normal.

Dehydration at onset and during relapse may obscure the presence of anaemia by producing haemoconcentration. Conversely, in response to therapy haemodilution reveals an abnormal blood count. Plasma protein values confirm this.

The degree of anaemia is not correlated with the degree of glossitis or achlorhydria, though glossitis and anaemia appear at the same time—i.e., at the beginning of remission.

Liver therapy has less effect on the anaemia than on other aspects of sprue. Reticulocytosis is poor and delayed, and is comparable with that in tropical megalocytic anaemia rather than with pernicious anaemia.

Intestinal Absorption during Relapse and Remission Phases

The following brief statement is based upon fat balances, chylomicron counts, blood-sugar curves, and nitrogen balances performed with Major D. A. K. Black, Major R. Clutton, and for P. Fourman on cases from series B80, fully described where.

relapse, diarrhoea is always a prominent symptom, and is accompanied by failure of absorption. In all cases fat absorption has been found grossly diminished as judged by fat balances. Sugar absorption is diminished as judged by flat blood-sugar curves, and in one case a negative nitrogen balance was found, due to increase of faecal nitrogen.

Electrolytes are deficiently absorbed, as judged by excess of faecal sodium with low blood levels. Serum iron, too, was low in one case at the end of a relapse, and rose to normal in remission. Plasma volumes are low in relapse, reflecting dehydration. There is thus evidence that protein, fat, carbohydrate salts, and water are deficiently absorbed in this phase. Whatever the primary absorption defect may be it is rapidly overlaid by secondary deficiencies due to diarrhoea, which is, however, an integral part of this disease.

In the remission phase on diet alone, improved absorption is reflected in gain of weight; chylomicron counts become normal long before steatorrhoea disappears; fat absorption does not improve in proportion with the clinical condition, cessation of diarrhoea perhaps entirely accounting for it. In remission with liver therapy, fat absorption is again only slightly improved; it does not become normal. Blood-sugar curves may improve markedly, but this is not constant.

Ten nitrogen balances showed all such cases to be in positive balance, and plasma proteins rise rapidly to normal.

The rapid improvement of the stools with liver therapy suggests marked increase of water absorption.

Summary and Conclusion

The diversity of symptoms in sprue as seen in British soldiers in India has been found to be presented in two groups: (a) the symptoms of onset or relapse consisting of diarrhoea, anorexia, weakness, vomiting, and loss of weight; and (b) symptoms of remission: these

are glossitis, cheilosis, distension, scaling of skin, with diminution of the symptoms of onset.

Transition from relapse to remission may be slow, with a mixed symptomatology. Fig. 5 shows diagrammatically the progress of

FIG. 5.—Diagrammatic representation of the course of sprue.

sprue from onset to recovery, death, or development of the classical syndrome, and its relation to malnutrition as it has been seen during these years.

During relapse dehydration is responsible for some of the clinical features. Barium meal examination has shown gross obliteration of the intestinal mucosal pattern. Absorption of protein, fat, carbohydrate, water, and salts is grossly affected.

During remission many of these defects remain for at least 1 to 2 months in spite of rapid gain in weight and marked clinical improvement. Macrocytosis with or without anaemia persists until weight reaches normal. Absorption of fats and sugars returns to normal only after 1 to 2 months, with or without liver therapy. Early in remission, however, improvement appears to occur in protein and water absorption, particularly with parenteral liver therapy.

Signs which may be interpreted as those of deficiency of B vitamins occur at transition from relapse or in early remission.

It will be apparent that remission is in no sense synonymous with cure—criteria for which it is not easy to state.

My thanks are due to the Director of Medical Services, India, for permission to publish this paper; and to Col. H. E. Knott, A.M.S., Officer Commanding, 3 Indian Base General Hospital.

SURGERY AND THE RELAPSE RATE OF MALARIA

BY

WILFRED KARK, M.B., F.R.C.S.Ed.

Lieut.-Col., R.A.M.C.; Officer in Charge of a Surgical Division

It is generally believed that surgical operations commonly precipitate a relapse of fever in a subject infected with malaria. Manson-Bahr (1941) emphasizes that surgeons should keep the possibility of post-operative relapse constantly in mind. Napier (1943a) considers it advisable, even in cases of possible latent infection, to give a course of cinchona as a routine measure before a surgical operation on anyone coming from a highly malarious area.

An attempt is made in this paper to assess the relapse rate of malaria in relation to surgical procedures; it is based upon personal case records collected during the past three years. The cases are considered in three groups.

Classification of Cases

Group I consists of patients having a history of pre-operative malaria, and also those without such history but in whom an early post-operative attack was suggestive of a previous latent malaria. Manson-Bahr (1941) emphasizes that surgeons should keep the possibility of post-operative relapse constantly in mind. Napier (1943a) considers it advisable, even in cases of possible latent infection, to give a course of cinchona as a routine measure before a surgical operation on anyone coming from a highly malarious area.

Group II refers to those cases, with and without a past history of malaria, submitted to operative surgery after the conclusion of a course of suppressive antimalarial treatment and either after or during the terminal "blanket" treatment. The preventive malarial regime consisted of mepacrine 0.1 g. twice daily for the first three days, followed by 0.1 g. once daily for as long as exposure in malarious "battle" areas continued. This suppressive course was then concluded by a "blanket" of mepacrine, 0.1 g. thrice daily for five days; no drug for two days; and pamaquin 0.01 g. thrice daily for three days. There were 147 operations in this group. The cases, as well as those in Group I, were observed in a "rear" hospital area.

Group III consists of surgical cases with or without a previous malarial history, evacuated from battle areas in which all personnel had been treated with daily suppressive mepacrine for a considerable

period. This mepacrine, 0.1 g. per day, was continued throughout the period in hospital, pre- and post-operatively. In this group there are some 1,900 cases. All were observed in a "forward" hospital area.

The relapse rate is considered in relation to major and minor surgery. The distinction is made dependent upon the time taken for the operation: a duration of less than 20 minutes is regarded as minor, and an operation lasting longer than this time is regarded as major. On this basis similar operations may fall into either class: e.g., some appendicectomies and herniotomies are classified as minor, others as major. This method of distinction has, however, seemed the most satisfactory for the purposes of the investigation in that the time factor is probably more closely related to the degree and extent of surgical trauma than any other factors which would lend themselves to general and simple classification.

Group I: No Suppressive Treatment

The incidence of relapses and fresh attacks, their types, and the times of onset after surgical operation are given in Tables I and II.

TABLE I.—Incidence of Post-operative Malaria

Operation	No.	Post-op. Relapse	Post-op. "Fresh" Attack	Total
Minor	121	9 cases (7.4%)	4 cases (3.3%)	13 (10.7%)
Major	55	4 cases (7.3%)	1 case (1.9%)	5 (9.1%)
Total	176	13 cases (7.4%)	5 cases (2.8%)	18 (10.2%)

TABLE II.—Analysis of Relapses and Fresh Attacks

Operation	Type of Malaria	Time of Onset in Days after Operation	No. of Cases	Relapse or Fresh
Minor: 13 cases	B.T.	3	1	R
	B.T.	11	2	R
	B.T.	12	1	R
	B.T.	14	3	R
	B.T.	15	1	R
	Clin.	4	1	F
	B.T.	7	3	F
Major: 5 cases	Clin.	3	1	F
	B.T.	2	2	R
	B.T.	11	1	R
	Clin.	12	1	F

"Clin." refers to clinical malaria—i.e., having all the signs and symptoms and a typical reaction to treatment, but no identifiable malaria parasites in blood smears. In the two cases of relapse the previous attacks had been diagnosed as malignant tertian infections.

Relapse Rate

Definite conclusions as to the relapse rate due to surgery are not possible because of a number of problematic features of such an assessment. The most notable difficulty in this regard derives from the fact that the investigation was conducted in an endemic area with an appreciable malarial incidence. In the medical division of the same unit, during the period under review for this group of cases, there were 1,824 fresh cases and 2,285 relapses of malarial fever; and these figures represent approximately one-quarter of all admissions on the medical side. It thus becomes doubtful whether the post-operative attacks were in fact precipitated by the operation or whether they were either fresh or relapsing fevers having no specific relation to the surgical event. In the tables in this paper the heading "Post-op. Relapse" is used to indicate an attack of malarial fever in a case with a history of pre-operative malaria: it could be a relapse or a fresh infection, the former being the more probable. The heading "Post-op. Fresh Attack" refers to the first clinically appreciable malarial fever that has been diagnosed. This attack might also be a relapse—the original infection having been a subclinical one—or a true fresh infection; here the latter contingency is the more probable.

Another element of doubt arises in that the post-operative period, during which it was assumed that the relapse might bear causal relationship with the operation, was defined as 15 days. This exceeds not only the minimum latent period but also the usual incubation period for benign tertian infection—according to Napier (1943b) 8 and 14 days respectively; but this period of 15 days was chosen in order to include the possible influence of various post-operative states (e.g., non-malarial fever, dehydration, exhaustion, and other complica-

tions arising within a week or so after the operation) which in themselves might be regarded as essential precipitating causes of the relapse.

The two features, the local endemicity and the allowance of a period in excess of the average incubation time, would in this investigation tend to raise the figure of the post-operative relapse rate beyond that proportion actually precipitated by the operation; but, even disregarding these influences, the total incidence of relapses amounts to 10%—a surprisingly low figure in view of the expectation of a higher relapse rate as implied by current teaching.

The time of onset of fever is recorded in Table II. The earlier the onset of fever after operation the more culpable does the latter appear as the precipitating factor; and this seems more especially to be the case when the onset of a benign tertian infection occurs within eight days—i.e., the minimal incubation period for this type. Of the 15 cases of post-operative benign tertian fever, 6 occurred within such a period; if the clinical malaria cases be included the ratio becomes 9 early post-operative attacks out of the total of 18. These figures of the earlier relapses, rather than the totals, may be regarded as a truer index of the proportion brought about by the surgical operation. However, even this index is presumptive and not definite, in view of the possibility of fresh infection having been acquired within a few days prior to operation.

Influence of Major and Minor Surgery

The relapse rates following major and minor surgery afford a comparison of significance. If the extent and the duration of the surgical trauma were important causative factors the proportion of relapses occurring after major surgical operations might be expected to exceed that after minor surgery. The incidence in this series of cases does not support such a contention. As the records in Table I demonstrate, the relapse rates after both major and minor surgery are almost identical.

Effect of Anaesthesia

The post-operative incidence of malaria in relation to the types of anaesthetic employed is analysed in Table III.

TABLE III.—Post-operative Malaria in Relation to Anaesthesia

	Intravenous Pentothal	Inhalational	Spinal	Local
Total anaesthetics	77	38	31	30
No. of attacks after minor operations	5	2	1	5
No. of attacks after major operations	2	1	2	0

The number of cases is not sufficient to allow of definite deduction; but there is the suggestion that the proportion of attacks of malaria after local analgesia is higher than after other anaesthetics. The 5 attacks after local analgesia represent a ratio of 1 in 6 cases; for the other anaesthetics the ratio is roughly 1 in 10 to 12 for each variety. It is noteworthy that the local analgesic used contained adrenaline, and that all five cases were minor operations. This finding provides a hint for caution in the use of even minute quantities of adrenaline in operating upon patients who may have quiescent malarial fever.

Type of Relapse

A great proportion of post-operative attacks were due to benign tertian infections: 15 out of 18 were identified as this variety; the types of the remaining 3 were not identified. The incidence of the pre-operative types of infection is given in Table IV.

TABLE IV.—Incidence of Types of Pre-operative Malaria

Type of Malaria	No. of Cases
Benign tertian	64
Malignant tertian	30
Benign and malignant	42
Quartan fever	1
Clinical	11
	148

Comparison between Tables II and IV shows that out of the total of 110 cases of B.T. infection (i.e., 106 with a pre-operative history plus 4 possible latent infections) there were 15 relapses; whereas out of 72 malignant tertian cases there were but two

relapses, the type of which, though not identified during the post-operative attack, might have been malignant. This relative incidence of B.T. relapse accords with the general and far greater tendency of this type to relapse quite apart from surgical influences, and the comparative figures provide no evidence, either way, of surgery as a precipitating factor.

Influence of Immunity

All the patients to whom the figures in Group I refer were British troops. The data collected for Indian troops have not been used in this paper because of the unreliability of the past history: "buchar"—i.e., fever—of any origin is apt to be ascribed by Indian troops to malaria. It is of interest, however, to record that, out of roughly 400 cases observed, the post-operative attacks of malarial fever amounted to between 5 and 6%—i.e., approximately half the relapse rate found among British troops. The lower rate among Indians is an expected finding in view of the greater numbers that have acquired an immunity by long residence in endemic areas.

The influence of the factor of immunity, or relative immunity in which there is a lack of febrile response, in so far as it affects post-operative relapse rates in British personnel, may be assessed by consideration of cases having a history of numerous pre-operative attacks. These cases have been abstracted, and the details of the number of attacks which occurred during four half-yearly periods prior to operation are recorded in Table V.

TABLE V.—Cases with Frequent Pre-operative Attacks

Pre-op. Period	No. of Pre-op. Attacks	Case Incidence	Post-op. Relapse
6 months	3 4 to 5	8 7	—
12 "	3 4 to 5 6 to 7	7 9 3	—
18 "	3 4 to 5 6 to 8	3 6 3	—
24 "	3 4 to 6 7 to 10	7 9 5	1 × R.-B.T.

The single relapse after 67 operations is in marked contrast to the remaining cases in this series—viz., 17 post-operative relapses in 109 cases in which there had been less than three attacks during the two-year period preceding operation. The contrast provides very suggestive evidence of the acquisition of immunity which reduces the liability to post-operative relapse of malarial fever. Table V further indicates that, even during such short periods as 6, 12, and 18 months prior to operation, 3 or more attacks of fever appear to confer a degree of immunity.

Influence of Proximity of Most Recent Attack

The liability to post-operative relapse relative to the proximity of the latest pre-operative attack is indicated in Table VI.

TABLE VI.—Proximity of Pre-operative Attack Relative to Post-operative Relapse

Type of Malaria	No. of Cases having an Attack within a Pre-operative Period of:						Totals	
	1 mth.	2 mths.	3 mths.	4 mths.	5 mths.	6 mths.	Cases	Relapses
B.T. ..	19 (2R)	3 (1R)	6	7 (2R)	8 (1R)	5 (2R)	48	8
M.T. ..	5	1	5	1	4	17	17	—
B.T. and M.T. ..	—	—	—	—	—	3	3	—
Clinical	1 (1R)	—	1	2	—	2	6	1
Total ..	25 (3R)	4 (1R)	12	10 (2R)	9 (1R)	14 (2R)	74	9

The figures in parenthesis give the number of post-operative relapses.

Out of a total of 13 post-operative relapses 9 occurred in the 74 cases in which there had been an attack of fever within the 6 months prior to operation—an incidence of about 12%. The remaining 4 relapses occurred in the 102 cases in which there had not been a pre-operative attack within this period—an incidence of about 4%. There is thus some evidence that post-operative relapse is more likely to occur when there has been a recent—within 6 months—pre-operative attack. Corre-

lation with the data given in the preceding section on the influence of immunity brings the conclusion that the possibility of post-operative relapse is enhanced by the occurrence of one or two attacks during this period of six months, but that the occurrence of three attacks markedly reduces it.

Group II: Surgery after Suppressive Treatment

In this group the period of observation after operation was not limited to 15 days; a longer period was allowed in order to cater for the effects of "blanket" treatment, which was often begun at the time of operation, and which would tend to delay the onset of relapse. The findings in this group of cases are recorded in Table VII.

TABLE VII.—Relapse Rate Following Suppressive Treatment

Past History	No. of Operations	No. of Post-op. Attacks	Type	Time of Onset	
				After Op.	After Completing "Blanket" Course
Previous malaria, positive	68	6 (9%)	6 × B.T.	8 wks.	6 wks.
				14 days	20 days
				14 "	5 "
				14 "	21 "

With reference to the 79 cases in which there was no history of previous malaria the significance of the 5 post-operative attacks is not readily calculable; for, apart from the possibility of a post-operative fresh infection having occurred, the proportion of cases with a previously suppressed malarial infection is unknown. The post-operative incidence of 6% is, however, an indication that this particular form of suppressive and "blanket" treatment cannot be regarded as assuring freedom from attacks after surgical procedures. This is more strongly indicated by the figures of the cases which did present a history of previous malaria. In these 68 cases there was a relapse rate of 9%—a proportion closely similar to that found in Group I, in which suppressive treatment had not been given. It therefore appears that the relapse rate of malaria following surgery is not affected by previous suppressive and "blanket" treatment of the type used in the Group II series of cases.

Of the 11 post-operative attacks, 6 followed major and 5 followed minor operations—a finding in agreement with that in the Group I series, where there was also no appreciable difference in the influence exercised by the two grades of severity of surgical operation.

Group III: Surgery and Continued Suppressive Treatment

This group consists of some 1,900 surgical cases seen in a "forward" hospital during the 1945 campaign season. They were admitted to the hospital after 3 to 14 days from the time of being wounded. In addition to their wounds, the great majority of patients had undergone severe physical exertion, followed by evacuation over long distances by road, air, rail, and river steamer. The battles had taken place in areas which were hyperendemic for malaria and in which unprotected personnel developed nearly 100% malarial infection. Almost every patient had had at least one operation before coming under my observation, and 743 were submitted to further operative treatment. All the patients had been taking suppressive mepacrine, 0.1 g. daily, for a considerable time, and this was continued during the evacuation stages and throughout the period of observation in hospital.

Two cases of post-operative malaria occurred; in both there was reason to believe that the men had evaded taking the daily dose of mepacrine. There is thus strong evidence that this form of treatment suppresses malarial fever even in the presence of severe trauma, prolonged physical strain, and extensive surgical operations.

Summary and Conclusions

This paper records observations upon the relapse rate of malarial fever in relation to surgical procedures.

In a series of 176 surgical operations performed on patients with a history of previous malarial infection, and to whom neither suppressive nor prophylactic antimalarial treatment was given, there was

post-operative attack of malarial fever in 10% of cases. The findings under which observations were made render it certain that this figure of 10% is in excess of the relapses brought on by local operation; and the investigation tends to throw doubt upon the validity of the assumption that surgery commonly precipitates relapses of malarial fever.

The relapse rate was practically the same whether the surgical operation had been of major or minor variety.

Local analgesics containing adrenaline were followed by a higher proportion of attacks of fever than were other forms of anaesthesia. The relative incidence of the types of post-operative relapse compared to the general relapse rate, and was predominantly due to malignant tertian parasites.

Three or more attacks of malarial fever during a period of two years preceding operation appeared to confer a degree of immunity to reduce the incidence of post-operative relapse.

A first or second attack within a period of six months preceding operation seemed to increase the liability to post-operative malaria. The findings in the first series of cases are compared with those found in 147 operations upon patients who had received and commenced suppressive treatment before operation. The post-operative relapse rate in cases with a history of pre-operative malaria in this second group was found to be practically the same as that in which suppressive treatment had not been administered.

In the third group of 1,900 surgical battle casualties suppressive treatment, instituted a considerable time before the battle trauma, continued throughout the period in hospital, virtually eliminated post-operative malaria.

VINESTHENE ANAESTHESIA FOR REPAIR OF HARE-LIP AND CLEFT PALATE

BY

PHYLLIS F. L. DAPLYN, M.R.C.S., L.R.C.P., D.A.
Anaesthetist, E.M.S.

Operations for the repair of hare-lip and cleft palate have in the past presented the anaesthetist with many difficulties. The patients are small babies or very young children, and therefore require more careful handling than adult patients; there is considerable interference with the airway; and there is the ever-present danger of blood finding its way into the air passages. The introduction of endotracheal anaesthesia solved the problem of keeping the airway open, but in the early days the anaesthetic vapour was delivered through a rubber catheter to the region of the larynx, and a free passage for returning air had to be assured. It was not until the modern method of to-and-fro intratracheal anaesthesia came into use that it was possible to pack off the larynx adequately, and so eliminate the danger of inhaled blood and allow the surgeon to have complete control of the field of operation. Ether, or gas-oxygen-and-ether, is the common anaesthetic chosen, but lately the use of vinesthene with gas and oxygen has been found to give even better results.

Properties.—Vinesthene is divinyl ether— $(CH_2:CH)_2O$ —to which has been added 3.5% absolute alcohol and 0.01% of a non-volatile oxidation inhibitor to render it less volatile and more stable. It is decomposed by acids, with the formation of aldehydes, one being formaldehyde, so it is considered safer to use only freshly opened bottles of the drug; like other ethers, it decomposes when exposed to light and air. Vinesthene is highly inflammable and as explosive as ethyl ether when mixed with air, oxygen, or nitrous oxide.

Some Aspects of Vinesthene as an Anaesthetic

Compared with other anaesthetic substances vinesthene possesses various advantages. It is less irritating than ethyl ether or ethyl chloride, causing very little salivation, and produces no nausea or vomiting after short administrations, and rarely very slight vomiting after longer administrations. In one series of 364 patients of varying ages, but consisting mostly of dental cases, no vomiting was reported (Goldman, 1936). Unlike chloroform, vinesthene does not cause any cardiac or respira-

tory depression. The induction is quick and recovery remarkably rapid.

On the other hand, vinesthene is a very potent anaesthetic, and it is as well for the anaesthetist to become really familiar with the drug in minor surgery before using it for lengthy operations. This was stressed when the substance was first investigated in this country (Shipway, 1935), and again by later workers. Ravdin *et al.* (1938) say: "It is exceedingly potent, and even though the traditional margin of safety is wide, the lethal concentration is such that the anaesthetic should be administered with due regard for its potency."

Some investigators have found that vinesthene may produce liver damage. Orth *et al.* (1940), for instance, found that weekly administrations of vinesthene to dogs produced central-zone necrosis of the liver and a progressive decrease of urea-clearance values, and a case of hepato-renal damage has been reported in a patient who had a second administration of vinesthene, lasting 104 minutes, ten weeks after the first administration, lasting 40 minutes (Hawk, Orth, and Pohle, 1941).

Ravdin (Ravdin *et al.*, 1937) has suggested that vinesthene should be used for short administrations only, as he believes that liver necrosis may follow long administrations even when every precaution to prevent anoxaemia has been taken; and he regards vinesthene as more toxic than ethyl ether. As a result of later work (Ravdin *et al.*, 1938) he and his fellow workers consider that vinesthene is not contraindicated in the presence of renal or cardiac disease, as there is no evidence that further damage is caused in such cases.

More recently vinesthene has been used extensively for war surgery by one anaesthetist (Ogus, 1941), who records the almost daily use of this substance for a year by open and closed methods. He specially commends the convenience of administration under war conditions, the lack of nausea and vomiting even in the case of patients with full stomachs, the rapid induction and recovery. He considers vinesthene combined with gas and oxygen to be superior to gas-oxygen-and-ether, but is careful to observe the safe dose limit of no more than half an hour's administration, set by the Council of Pharmacy and Chemistry of the American Medical Association, and adds a limit of 50 to 75 ml. by the open method at one time.

Convulsions occurring under vinesthene anaesthesia have been recorded in America and in this country. Dawkins (1940) published nine cases of convulsions—four occurring in patients who were undergoing major operations and five among children in the dental department. Another isolated case has been recorded (Boston, 1940), and I myself have seen two cases occurring in children after vinesthene anaesthesia for dental extraction. These convulsions resemble ether convulsions except in the fact that those following a short administration of vinesthene (e.g., for dental extraction) may occur some few minutes after the child has recovered consciousness. Ether convulsions always appear to be controlled by the intravenous injection of a barbiturate, and none has been recorded after an induction with a barbiturate. But the four cases reported by Dawkins (1940) showed convulsions with vinesthene following induction with hexobarbitone (evipan).

The recent work carried out by Williams and Sweet (1944) throws a new light on the subject of anaesthetic convulsions. They investigated, by means of electro-encephalography, 22 cases in which convulsions under anaesthesia had occurred, and obtained abnormal results in about three-quarters of them. Paroxysmal outbursts of abnormal waves were seen in over half, and larval epileptic attacks in a quarter, of the cases. The incidence and nature of the abnormal results were identical with those found in a large number of idiopathic epileptics, and were not considered to be the result of the convulsion. They came to the conclusion that all the evidence presented supports the view that anaesthetic convulsions are primarily due to an inborn but latent epileptic liability; that the factors which precipitate a convulsion in these predisposed persons vary between individuals, but many of the factors which have been incriminated are well-recognized precipitants of epileptic fits in conscious subjects; and that the main difference between fits lies in the degree of predisposition to convulsions, the many factors which arise during anaesthesia being merely precipitants of the convulsion. Williams and Sweet (1944) point out that anaesthetic convulsions are more rare among epileptics than among normal patients, and give the explanation that the

epileptics are probably receiving anticonvulsant treatment. In view of this it may be that the four cases reported by Dawkins (1940) did not receive enough barbiturate to overcome their predisposition to convulse.

Latent epileptics exist in considerable numbers in the population, according to the work of Lennox, Gibbs, and Gibbs (1940), who found that 2.4% of the relatives of epileptics develop epilepsy and 60% show a dysrhythmia with electroencephalography, latent epileptics therefore outnumbering overt epileptics by 25 to 1. It is perhaps astonishing that anaesthetic convulsions are not seen more often than they are. The conclusion would seem to be that the correct combination of factors leading to convulsions must be present for each individual, the inborn convulsive tendency and the anaesthetic being constant factors, and the precipitating cause or causes—e.g., toxæmia, low blood sugar, high body temperature, pain, etc.—varying in each case.

Most of the cases investigated by Williams and Sweet (1944) had been anaesthetized with ethyl ether in combination with gas and oxygen, and ether is known to produce persistent high-voltage discharges during induction. It would be interesting to know whether vinesthene has a similar effect on the cortical rhythm.

Present Series

In this series of 50 cases, 20 patients underwent repair of hare-lip and 30 repair of cleft palate. These patients were not picked, but formed the routine cases on the operating list at an E.M.S. children's hospital. The ages of the hare-lip cases ranged from 3 to 19 months, and those of the cleft-palate cases from 1 year 3 months to 8 years. The latter case, however, was an exceptional one, and the average age of the cleft-palate cases was 2.8 years.

Details of Cases

Operation	No. of Cases	Average Age	Length of Administn.	Chest Complications	Vomiting		Results
					Yes	No	
Hare-lip	20	5.4 mths.	20-30 min.	Nil	0	20 (100%)	Good
Cleft palate	30	2.8 yrs.	30-40 "	"	2 Very slight	28 (93.3%)	"

Method Used

The premedication was atropine only, and each case was intubated with a Humby tube (Fig. 1), a reinforced tube (Fig. 2), or a Magill tube with the special angled connexion

FIG. 1.—The Humby tube.

FIG. 2.—Reinforced tube.

comes this trouble, as it bridges the gap, or a small roll of gauze packed into the cleft will also serve.

The anaesthetic in each case was gas, oxygen, and vinesthene from a standard Coxeter machine, fitted with a Goldman drip vaporizer (Fig. 5). This allows very fine adjustment and perfect control that the anaesthesia can be lightened or deepened in a matter of seconds. After intubation the anaesthesia never

FIG. 3.—Magill tube with angled connexion.

needs to be deeper than the first plane of the third stage, and at the close of the operation the patient is ready to gag and cough as soon as the tube is removed. This relieves the nursing staff of much anxiety during the return trip from the theatre to the ward.

As will be seen by the accompanying Table, the hare-lip cases averaged 20 to 30 minutes under the anaesthetic and the cleft-palate cases 30 to 40 minutes.

FIG. 4.—Broad blade for the laryngoscope.

FIG. 5.—Goldman drip vaporizer.

Results

The results were uniformly good. There were no chest complications, and very slight vomiting occurred in only two of the cleft-palate cases. Healing in every case was by first intention. The ward sisters reported that the children were easy to manage and in very good shape following operation. Their opinion was that vinesthene was preferable to ether for these cases and that the children were much brighter and in better general condition than when ether was used.

Summary

Anaesthesia for the repair of hare-lip and cleft palate is reviewed. The properties and some aspects of vinesthene as an anaesthetic substance are discussed.

A series of 50 cases of hare-lip and cleft palate anaesthetized with gas, oxygen, and vinesthene is reported, with the method used and the results obtained.

My acknowledgments are due to Mr. Denis Browne, under whose care were the patients in this series; and I wish to thank Sister Veridge, sister in charge of the theatres, for the loan of apparatus. The appliances shown in Figs. 2, 3, and 4 were designed by Mr. Denis Browne.

A CASE OF POLYNEURITIS DUE TO GOLD

BY

E. J. R. LEIPER, M.D., M.R.C.P.

Physician to an E.M.S. Hospital

Treatment by gold injections is considered to be of value in rheumatoid arthritis, in which it is much used. Toxic effects are unfortunately not uncommon. These may take different forms. In the following report one of the more unusual toxic complications of gold therapy is described.

Case Record

The patient, a woman of 52, was seen elsewhere in February, 1945, with a two-months history of pain and stiffness in the joints, beginning in the hands and spreading rapidly to the left shoulder, cervical spine, knees, and right ankle. At the time moderate peritendinous swelling was noted in the metacarpo-phalangeal joints of both hands. The knees were also somewhat swollen, but the other affected joints showed merely restricted painful movement. The S.R. was 60 mm. in an hour (Westergren). Nothing of significance was found elsewhere, and a diagnosis of early rheumatoid arthritis was made. Treatment included physiotherapy and 13 injections of 2 g. of myocrisin (sodium aurothiomalate), the first three at weekly intervals and thereafter at five-day intervals. Considerable benefit resulted and the pain and swelling became steadily less. Towards the end of the course the patient noticed some soreness of the mouth, but thought it so insignificant that she did not mention it. On the day after the last injection, however, she also experienced some difficulty in getting up from a chair and in climbing steps. This was quickly followed by an increasing sense of weakness and uselessness throughout both legs. Some days later the arms became affected in the same way, though to a lesser degree, movements at the shoulders, as on raising the arms, being first involved. The feet and the hands felt numb, and tingled "as if they had been stung," except in the finger-tips, which ached, no complaint was made of pain. A twitching of the face was noted as well as occasional sensations of heat in the trunk. These symptoms became so incapacitating that soon the patient was reduced to a helpless state and confined to bed, unable to feed or dress herself, or even to sit up or turn round without help.

She was first seen by me seven weeks after the last injection of myocrisin. By that time all pain, tenderness, swelling, and stiffness had disappeared from the affected joints. Her general condition was fair, and, with the exceptions noted below, no abnormality was found in the cardiovascular, respiratory, alimentary, and urinary systems elsewhere. The blood count was normal. The mucous membrane of the mouth and pharynx was studded with numerous tiny superficial ulcers.

The mental faculties were normal, and the patient was intelligent and co-operative. All the cranial-nerve functions were normal, as were the fundi. In spite of the patient's complaint of twitching of the face, this was not observed, and there was no facial weakness.

Motor System.—There was a widespread symmetrical flaccid paresis affecting all four limbs, more severe in the legs than in the arms, and accompanied by a mild degree of wasting of the muscles. Though nowhere absolute, the weakness was well marked in all the muscle groups, and was especially severe proximally. In the hips and pelvic girdle this led to inability to sit up or even to turn over in bed, and the patient had to push herself up bodily with her arms on the sides of the chair when rising from it. Standing was as possible but extremely unstable, while walking was quite impossible. From weakness of the shoulder muscles, elevation at

the shoulders was limited to about 60°. There was also considerable ataxia of the upper limbs in the finger-nose test—doubtless due, at least in part, to the deep sensory loss described below. The neck and trunk muscles appeared unaffected.

Reflexes.—The supinator, biceps, triceps, knee, ankle, and abdominal reflexes were all absent. The plantars were feeble but flexor. The pupillary reflexes were normal, as were also the sphincters.

Sensory System.—Objective sensory disturbances were much less evident than motor loss. Thus no impairment could be demonstrated in the sensation of the skin to cotton-wool, pin-prick, heat and cold, nor in deep pain sensibility, but there was some loss in the sense of position and passive movement in the hands and feet, and vibration was not fully appreciated in the distal parts of the limbs.

The cerebrospinal fluid was clear and colourless, under normal pressure, and contained 290 mg. of protein per 100 ml. and 45 lymphocytes per c.mm.

Treatment was expectant and included rest in bed, means to prevent deformity such as footdrop, and, as is customary in polyneuritis, large doses of yeast by mouth to supply the vitamin B complex. Later, massage to the muscles and active and passive movements were added. Under this regime spontaneous recovery followed. Paraesthesia and objective sensory loss had almost completely disappeared in three weeks, but recovery of power was a much slower process. It occurred earliest and was most advanced in movements at the distal joints. In six weeks the patient was just able to get up from a chair and to stand without using her arms, and her tendon reflexes were still absent. It was not until a further two months that there was full clinical recovery with normal muscular power, and even then the knee- and ankle-jerks could not be elicited and the tendon reflexes were very sluggish. The stomatitis was also slow in healing, but eventually it did so completely.

Discussion

From the clinical and other features it is evident that this is a case of polyneuritis, and there is little reason to doubt that the gold injections were responsible for the condition as well as for the stomatitis. In an exhaustive review of the toxic effects of chrysotherapy Sundelin (1941) includes polyneuritis among a wide variety of nervous lesions. He points out that either the central or the peripheral nervous system may be involved. Cerebral symptoms are frequent, ranging from simple depression through excitable restless states to frank psychoses with hallucinations and confusion; more localizing symptoms also occur, such as aphasia, hemiparesis, and bilateral central facial paralysis. In the peripheral nervous system damage to a cranial nerve is sometimes seen, either alone or along with other neurological features. Some of the lesions—e.g., unilateral blindness—have occurred in purpuric states due to gold and may have been caused by haemorrhage; but others, such as unilateral facial paralysis, abducent nerve paralysis, and nerve deafness, are evidently due to a localized toxic neuritis. Vertigo, of similar peripheral origin, though also possibly due to disturbance of more central labyrinthine connexions, may also occur, as well as diplopia and inequality of the pupils. Local involvement of a peripheral nerve is further exemplified by cases which have developed herpes zoster during treatment with gold. More widespread forms of neuritis, like polyneuritis of other aetiology, affect all four limbs symmetrically. They resemble the case here recorded and show both motor and sensory features as well as changes in the cerebrospinal fluid in the direction of an increase in the protein and cells. Flaccid paralysis with loss of reflexes and wasting, though varying somewhat in intensity and distribution, is always a prominent feature and may be both widespread and severe. Objective sensory loss also occurs, as well as pain and paraesthesia. Some authors have stressed the presence of pain in the limbs in gold polyneuritis and consider it may be the sole indication of damage to the peripheral nerves during treatment by gold. If so, this is in marked contrast with the present case, in which pain was minimal and muscular tenderness almost absent.

It will be seen, then, that the possible toxic effects of gold upon the nervous system are many and varied. In Sundelin's series, out of a total of 964 toxic manifestations of gold 107 were referable to the nervous system. From their nature these neurological side-effects, except in their mildest forms, are more or less serious. At times they may be exceedingly alarming and may even endanger life, or they may be succeeded by permanent sequelae, such as deafness. Fortunately, however, most cases recover completely, sometimes remarkably rapidly

in the course of a few days, at other times only after a long and tedious illness attended by much disability, as in the case recorded.

As at present there is no specific treatment for the toxic effects of gold, and as they occur in a regrettably high proportion of cases treated in this way, the question of prophylaxis assumes particular importance. In an endeavour to reduce them to a minimum various schemes of administering gold have been suggested. A study of the literature shows how great is the diversity between these schemes as regards the size, number, and spacing of the individual doses, but, on the whole, opinion now seems to favour relatively small doses as being less toxic than, and as efficacious as, the larger doses previously given. This was the view expressed at a meeting of the American Rheumatism Association (1941), where a total of 1 g. was suggested for a course and where, in respect of toxicity, calcium aurothiomalate was very favourably compared with sodium aurothiomalate. Douthwaite (1944) likewise recommends a total maximum of 1 g. and suggests, as a course, 6 weekly injections of 0.02 g. of an oily suspension followed by 10 doses of 0.05 g. and, if necessary, a further 2 doses of 0.1 g.; he emphasizes the necessity for repeated courses—e.g., four in two years—to prevent relapse. Another common scheme consists of 10 weekly doses of 0.1 g. preceded by 2 doses of 0.01 g. and 0.05 g. respectively. By such standards the course administered in the present case—13 injections of 0.2 g. of myocrisin in 64 days—must be judged an intensive one. At the same time, it must be admitted that toxic effects are by no means entirely confined to those receiving a relatively heavy dosage. There appears to be great variability in the susceptibility of individuals to gold, so that even a few injections or a small total dosage may at times be sufficient to provoke unpleasant reactions. Even when all precautions are observed as regards dose, it remains true that the toxicity of gold is unpleasantly high, and some really effective means of preventing or counteracting its poisonous effects is much to be desired.

Summary

A case of polyneuritis due to gold used in the treatment of rheumatoid arthritis is recorded.

The toxic effects of gold upon the nervous system are briefly discussed.

A CASE OF MYIASIS DUE TO WARBLE-FLY LARVAE

BY

ARTHUR SMITH, M.B., M.R.C.S., D.O.M.S.

First Assistant, Ophthalmic Department, Royal Hospital, Sheffield

AND

DESMOND P. GREAVES, M.B., Ch.B., B.Sc.

Ophthalmic House-surgeon, Royal Hospital, Sheffield

Myiasis in man due to the larvae of flies, particularly various species of Diptera, is common in many parts of the world, especially in the Tropics. The warble-fly, however, is responsible for very few of these cases. Of the two varieties—namely, *Hypoderma bovis* and *Hypoderma lineatum*—we have found only six fully authenticated cases caused by the latter variety. The first was recorded in America in 1889 by Kane and Freeman, followed by another in 1910 by Miller; two cases from France by Topsent in 1901 and 1909 respectively; a fifth from Germany in 1913 by Gläser; and the sixth (the first in this country) by F. W. Style in 1924.

Case Report

The patient, a boy aged 7, lives on a farm in the Hope valley, in Derbyshire. He attended the ophthalmic out-patient department of Sheffield Royal Hospital on Jan. 14, 1946, with a swelling of the right upper eyelid and supraorbital region which appeared suddenly 14 days previously. The swelling was diffuse, smooth, and regular,

and extended 1½ in. (3.8 cm.) above the eyebrow and the whole length of the orbital margin. It was soft but did not fluctuate, and it appeared to be partially connected to the skin but not to the deeper tissues. There was no tenderness, erythema, or regional adenitis, and he showed no constitutional disturbance. He complained only of persistent visual obstruction, obviously due to the oedema. The eye was slightly proptosed and markedly depressed, diplopia being prevented by the total pseudoptosis. Ocular upward movement was restricted, but there was full range of all other movements. The right disk was slightly paler than normal.

The following investigations were carried out the same day: E.S.R. 10 mm./hr., W.R. negative, x-ray appearances of orbit and sinuses normal; differential white cell count: myelocytes 1%, metamyelocytes 18%, polymorphs 57%, lymphocytes 19%, monocytes 3%, plasma cells 2%. On Jan. 25 the eyelids opened slightly, but by the evening became more swollen than before. On the 26th a tiny hole, like a pin-prick, was seen in the centre of the skin of the upper eyelid, from which small beads of blood-stained serum oozed out. The following day the brow and right frontal region became swollen and purplish, and a similar hole appeared in the skin about 2 cm. above the centre of the right eyebrow. The report from the aural surgeon at this time showed that there was no sinus infection.

He was admitted to hospital on Jan. 28, and sulphonamide and penicillin therapy was continued during the next six days together with the application of diathermy to the orbit twice daily. On Feb. 3 the swelling around the hole in the supraorbital skin was indurating but not fluctuating. Slight pressure extruded a few beads of pus, and further pressure resulted in the expression of a white

FIG. 1.—Photographic enlargement of the larva expressed from the boy's forehead. Size, 11 mm. long by 2.5 mm. diameter. The segmental markings and the spiracles at the posterior extremity are clearly seen.

spindle-shaped living larva, 11 mm. long and 2.5 mm. in diameter (Fig. 1). The clean-cut circular hole, about 1 mm. in diameter, was left exuding thin pus, which on culture proved to be sterile. It contained polymorphs and other white cells, the majority of which were eosinophils. A differential blood count showed: total white cells,

FIG. 2

FIG. 3

Fig. 2.—Photograph of patient three days after extrusion of the larva. The residual oedema and pseudoptosis subsiding.

Fig. 3.—Photograph of patient when discharged. There is fibrosis round the site of the first warble in the upper lid.

7,600 (polymorphs 34%, lymphocytes 36%, monocytes 2%, eosinophils 28%); the red cells were normal. On Feb. 11 another count showed: total white cells, 7,400 (polymorphs 43%, lymphocytes 46%, monocytes 2%, basophils 1%, eosinophils 8%). By Feb. 20 the white cell count had fallen to 5,600 (polymorphs 39%, lymphocytes 48%, monocytes 5%, eosinophils 8%). Another count on Feb. 27 showed: total white cells, 5,600 (polymorphs 44%, lymphocytes 48%, monocytes 5%, eosinophils 8%).

cytes 49%, monocytes 2%, basophils 1%, eosinophils 4%). The red cells were normal. Haemoglobin 90%, colour index 1.1, and the E.S.R. 4 mm./hr. By March 11 the eosinophilia persisted at 6%.

After expression of the larva the reactionary oedema quickly subsided (Fig. 2). By Feb. 26 a slight fullness of the upper lid was all that remained. The eye was no longer depressed, there was full range of ocular movement in all directions, and the diplopia test was negative. The fundus was normal and vision was 6/6 in both eyes. Deep palpation suggested the presence of a small spindle-shaped object nestling beneath the supraorbital margin just above the scar marking the puncture in the skin of the eyelid. In view of the possibility that this might be another larva, surgical exploration was carried out, but failed to reveal anything abnormal beyond some fibrosis (Fig. 3).

Life History of the Warble-fly

We are indebted to Prof. L. E. Eastham, Zoological Department, University of Sheffield, who identified the larva as *Hypoderma lineatum* in the second stage of its life cycle (Natwig, 1937; Ono, 1938). The full significance of this unusual form of myiasis can be appreciated only by considering the life history of the warble-fly (Warburton, 1922; Miller, 1910).

Warble-flies appear in hot sunny weather, most commonly in July in this country, but they may be found at any time between April and September. They are commonly known as gadflies owing to the terror and "gadding" they cause among cattle. They lay their eggs on the hairs of the hocks and along the flanks of recumbent cattle. The *H. bovis* lays its eggs singly, the *H. lineatum* in clusters of fourteen to a single hair. The eggs of *H. bovis* hatch out in four days; those of *H. lineatum* take a few days longer. The larva that emerges is 0.8 mm. long. It is segmented, covered with small spines, and provided at its anterior extremity with a pair of mouth-hooks separated by a median spear. With the help of this armory it enters the skin through a hair follicle and takes up its abode in the dermal connective tissue. Usually nothing is seen to indicate its presence until the warbles appear on the back of the animal seven months later.

During this period the larva travels in connective tissue, undergoing an uncertain number of changes in development by ecdysis. By the autumn it has arrived in the submucosa of the oesophagus, and during the winter months it migrates to the diaphragm, and thence along the ninth and tenth intercostal spaces so as to come to lie between the periosteum and the dura mater of the spinal canal in the lower dorsal region; here the larva is in an intermediate resting stage. This affords easy access to the saddle area of the back, the usual site for warble-tumours ("warbles").

The pin-hole opening in the centre of a warble is really a breathing-hole made by the larva through which it can draw air into the spiracles placed at its posterior extremity. The local tissue reaction produces a sero-purulent exudate on which the larva feeds until it is mature, when it emerges from its breathing-hole, falls to the ground, and quickly hardens to form a pupa. After five weeks the fly emerges from the pupa and is ready to lay its eggs and start the life cycle all over again.

Discussion

The mode of infection in this case is not known, but it is highly probable that the eggs or larvae became attached to the boy's clothing when in contact with recently infected cattle. The actual invasion of larvae may have passed unnoticed, beyond a slight and temporary skin irritation. This apparently was the only immediate discomfort felt by Gläser (1912-14), who accidentally infected himself whilst experimenting with *H. lineatum* larvae. He noticed that the newly hatched larva had disappeared into the skin within one and three-quarter hours.

The fact that the larva was expressed at an intermediate or immature stage supports the theory that these larvae do not reach the penultimate stage in the human host, such a habitat probably being unnatural for the mature development of the larva. That it rapidly grows in size soon after entering the skin was shown by Gläser, who stated that within four or five days the larva had grown to a length of 2.5 mm.; five months later he removed a typical oesophageal larva 7.5 mm. long from his own mouth. This suggests it was a mature

oesophageal larva. Animal experiments (Hadwen, 1915) have shown that only the largest oesophageal larvae of both species are ready to proceed at once to form warbles and that those less advanced continue their wanderings. Referring to human infection by *H. bovis*, Schoyen (1886), who collected a number of cases that had occurred in Norway during the previous hundred years, states that as a rule the larvae have undertaken long ramblings under the skin, always in an upward direction, previous to their appearance through openings in warbles on the upper part of the body (head, neck, shoulders, etc.). All of them lived in this manner for months, and the larvae came out during the winter, most commonly in February, but were always much too young to be hatched. We may conclude that the larva does not undergo its full life cycle in man. On the other hand, we must record that the larva from Style's case was described by Major Austin as being a penultimate-stage larva of *H. lineatum*; but he also states that the full-grown larva is of considerable size and many times larger than the specimen forwarded to him.

In our case there is no history of the subcutaneous wanderings characteristic of the "pre-oesophageal" larva. In all the published reports available of human infection, subcutaneous migration has been extensive and readily observed, usually before the larva reaches the oesophagus. Ordinarily the course of a migrating larva is not betrayed by any track, but occasionally, when sepsis has occurred, a greenish track marks the wake of the larva. The tracks are always confined to connective tissue. Migration is maintained partly to avoid encystment; the organism would die if encystment occurred before it reached the final warble stage. The disappearance of the warble from the upper eyelid in the present case may indicate either encystment and death of the larva with subsequent absorption, or a migration from the eyelid with possible reappearance later elsewhere. The steadily falling eosinophilia supports the first alternative. Another explanation, however, may be that the larva emerged from the warble on the eyelid unknown to the patient or his parents before he entered hospital. The possibility that other larvae are still present in the boy's body must be borne in mind and a watch must be kept for the appearance of other warbles.

It is doubtful whether the treatment instituted influenced the course of the disease.

It is stated that the warble-fly attacks two-thirds of all cattle in this country, causing severe loss of condition, reducing milk yields, and damaging one million hides a year. The high incidence demands effective preventive and curative treatment. It also suggests the possibility that other cases of human infestation by contact with cattle may have remained undiscovered or unrecorded.

It is worth noting that the Hope valley, in Derbyshire, suffered the worst "gadfly" epidemic for many years last summer.

Summary

A rare case of human myiasis due to warble-fly larvae is reported.

The life cycle of the warble-fly illustrates the tendency for the larva to migrate and form warbles.

Experimental evidence and case reports suggest that in man the life cycle of both species of warble-fly is inhibited.

Contact with recently infected cattle is the probable mode of infection.

Prevention seems to be the only treatment available in human or animal myiasis caused by warble-fly larvae.

We are indebted to Dr. J. W. W. Baillie, who originally referred the case to hospital, and to Mr. Gordon Mackie, Honorary Ophthalmic Surgeon to the Royal Hospital, Sheffield, for permission to publish this report.

VITAMIN C NUTRITION IN
NORTH-EAST ENGLAND

BY

JAMES BLACK, M.D., F.R.F.P.S.

Assistant Physician (Temporary), Sunderland Royal Infirmary

In the winter and spring months of 1943 an estimate was made of the vitamin C balance of 100 adults living in a mining town on the north-east coast of England. The findings may be of interest.

Harris (1939) noted that vitamin C subnutrition was increased during the 1914-18 war. Orr (1936) suggested that more than half of the population of Great Britain received less than the reputed optimum allowance of vitamin C. Harris (1940) found subnutrition prevalent among elementary-school children, and in 1942 he noted that nutrition among students and school-children was at a lower level than it had been before the war. Other reports of the nutritional state of various sections of the community have been published, but no recent findings have been noted from this area.

Rationale and Method of Investigation

The reader may be reminded that the minimum daily requirement of vitamin C for the preservation of health is in the region of 25 mg. (Abbasy *et al.*, 1935); that a normal adult on a middle or higher working-class diet excretes between 15 and 30 mg. a day (Harris and Ray, 1935); and that oral administration of a "test dose" of ascorbic acid to an undernourished subject results in its retention in the tissues until the deficiency is made good, while administration of the same dose to one who is well nourished results in the early overflow of a large part of that dose into the urine.

Cases suffering from any clinically recognizable disorder which *per se* could lead to an increased vitamin C demand and metabolism were excluded from the survey. In addition to clinical examination the B.S.R. was estimated in each case. One hundred intelligent and co-operative patients were selected, 38 being males and 62 females. Details of the present and past dietetic habits of each patient were obtained at the outset and correlated with the ultimate findings. No case included in the series developed an intercurrent infection. The ascorbic acid was administered by the "test-dose" method of Harris and Ray, the "test dose" being 700 mg. ascorbic acid per 10 st. (kg.) body weight. The vitamin C excreted in the urine ascertained by the method of Sendroy and Miller (1939), and the vitamin C content of the urine was made by against a freshly prepared standardized solution of chlorophenolindophenol.

Findings

(1) *Males*.—Of the 38 cases examined 35 responded briskly to test-dosing, the response coming on the first or second day. Three were sluggish in their response, the rise coming only on the third or fourth day. None showed clinical evidence of vitamin C subnutrition. The three cases with sluggish response were regarded as being unsaturated but not undernourished.

(2) *Females*.—Of the 62 cases 27 responded briskly on the first or second day. The remaining 35 were sluggish in their response and were distributed as follows: third day, 25 cases; fourth day, eight cases; fifth day, two cases. Slow response (and therefore presumably slightly depleted reserves) was found more frequently in those women whose husbands were living away from home than in those whose husbands were at home, the ratio being 5:1; and, conversely, the bulk of the women who responded briskly had their husbands living at home.

The clinical findings in one of the women with slow response were of interest. Her husband was in the Forces, her children had their midday meal at school, and she herself was living on an obviously inadequate diet. The response to test-dosing with ascorbic acid came on the fifth day. She was slightly under weight, and there were two large bruises on the extremities at the time of examination, which she attributed to slight trauma. There was no obvious pyorrhoea, but the gums were spongy and bled easily. Hess's test was positive, and there was a normocytic normochromic anaemia, the red cells numbering 3,200,000 per c.mm. and the Hb (Sahli)

being 65%. Unfortunately, continuous observation in this case was interrupted, but when the patient was seen again several months later the sponginess and bruising tendency had disappeared, Hess's test was negative, and the blood picture had improved, the red cells now numbering 4,200,000 per c.mm. and the Hb being 80%. In the interval she had had a more balanced diet and had taken ascorbic acid 200 mg. daily by mouth. No medicinal iron had been given. Her original state was due to general malnutrition and not to avitaminosis C alone. There is no relation between spongy bleeding gums and vitamin C deficiency unless this is so severe as to produce scurvy; and increased capillary fragility does not appear to be related to vitamin C deficiency. One must conclude that the improvement was due to the better diet and not to the ascorbic acid supplement.

Summary and Conclusions

The results of assessment of the vitamin C balance of 100 adults resident on the north-east coast of England are given. From a study of this comparatively small series one might say that: (1) The men on the whole were well nourished. (2) Many of the women had less satisfactory reserves. (3) Diminished reserves were found more often among those women whose husbands were living away from home than among those whose husbands were at home. (4) As would be expected, the quickest response was seen in those cases which had a satisfactory dietetic history. (5) Diminished intake of vitamin C was due to apathy or ignorance and not to poverty or non-availability of suitable foodstuffs. (6) Close inquiry should be made into the intake in all doubtful cases and advice on suitable diet given. A nutritious diet, with perhaps added ascorbic acid, is necessary in conditions where there is likely to be an increased vitamin C demand—e.g., toxic, infective, and traumatic states.

I would like to thank Dr. H. A. Cookson and Prof. F. J. Nattrass for their interest and advice.

Medical Memoranda

Gangrenous Enteric Intussusception in
Adolescence

The following case is considered to be worthy of record owing to its rarity. The management of the case also presented interesting features.

CASE HISTORY

The patient, a girl aged 14, was admitted to the Royal Victoria Infirmary, Newcastle-upon-Tyne, on Jan. 16, 1946. She gave a history of vomiting for five days, severe abdominal pain, and almost complete constipation, with the passage of blood per rectum for two days before admission. She was extremely dehydrated, with sub-normal temperature and a pulse rate of 126 per minute. On examination there was generalized abdominal rigidity, with marked central abdominal swelling. She was given three pints (1.7 l.) of intravenous glucose-saline before operation, which was delayed six hours for this purpose.

Through a right longitudinal rectus-splitting incision the abdomen was explored. A greatly distended loop of jejunum was found; this was 40 cm. long, and was delivered through the wound after the incision had been enlarged upwards. The intussusceptum and intussuseptum were both seen to be gangrenous, the former being perforated. The intussusception was resected, with end-to-side anastomosis, and the abdomen closed with drainage.

Ten pints (5.68 l.) of glucose-saline were given during the next 24 hours. The blood-urea estimation was 60 mg. per 100 ml. and serum chlorides 298 mg. per 100 ml. These tests were performed on Jan. 17. In the first 24 hours 15 oz. (425 ml.) of urine were passed. On the second post-operative day five pints (2.84 l.) of intravenous glucose-saline were given: urinary output was increased to 42 oz. (1.2 l.). Four days after operation the patient was taking fluids well by mouth, bowel sounds had returned, and flatus had been passed. On Jan. 22 a bile-stained discharge was observed on the dressing. By the next day the trickle had become a flood. Fluids by mouth were severely restricted and intravenous therapy restarted; four pints (2.27 l.) of glucose-saline and one pint (568 ml.) of plasma were given every 24 hours. Continuous suction was applied to the fistula, but some leakage occurred.

On Jan. 26 the patient's general condition was satisfactory. Skin tension was becoming troublesome and there was no sign of the tula closing; consequently it was decided to explore the anastomosis. It was then found that the antemesenteric border of the oximal loop had sloughed; the remainder of the anastomosis had healed satisfactorily. A mucosal fold was forming a valve over the distal loop. A further 2 in. (5 cm.) of bowel was resected and an end-to-end anastomosis was performed, as enough bowel could not be mobilized for any other type without breaking down protective adhesions. On account of disparity in the diameter of the proximal and distal loops the anastomosis was difficult. The wound was closed with silk sutures throughout and without drainage.

As expected, some leakage continued for a further 10 days. One pint (568 ml.) of plasma and four pints (2.27 l.) of glucose-saline were given every 24 hours until the sixth post-operative day, when the fistula was showing signs of becoming dry. Suction was unsatisfactory, and the skin was protected to some degree by a paste containing aluminium. A fortnight after the second operation the wound was completely healed. Continuous gastric suction was employed for two or three days after each operation. Small quantities of fluid were given by mouth throughout. Penicillin was administered for 10 days after the first and five days after the second operation. The patient was discharged from hospital on Feb. 28.

The pathological report on the specimen stated that there was no obvious tumour to account for the intussusception."

COMMENT

The interesting feature of this case is the length of time it is possible to keep the general condition of a patient satisfactory with intravenous therapy. This girl had very little nourishment by mouth from Jan. 11 to Feb. 6. She showed no clinical signs of hypoproteinaemia. Further, the inadvisability of being too conservative regarding the point of section of the bowel proximal to the intussusception was clearly shown.

No account of this case would be complete without praise for the nursing staff, whose care and attention largely contributed to the successful result.

Surgical Registrar,
Royal Victoria Infirmary, Newcastle-upon-Tyne.

Heterospecific Pregnancy as a Possible Cause of Erythroblastosis Foetalis

The following case seems to merit publication in view of certain unusual features.

CASE HISTORY

A full-time male infant was delivered spontaneously on Jan. 25, 1946, and found to be jaundiced. Suspecting erythroblastosis foetalis, samples of blood were sent to the Department of Pathology, Dundee. The infant's haemoglobin was 120% and the blood film showed evidence of erythroblastæmia, as many as 10 erythroblasts being found per oil-immersion field. This was the third pregnancy. The first child was illegitimate and is alive and well. The second child was 3 weeks prematurely delivered, in 1944, and lived 5 days. This child was diagnosed from a blood film as a case of erythroblastosis, but, unfortunately, serological examinations were not carried out, and necropsy findings were reported as inconclusive. The mother did not show any evidence of toxæmia of pregnancy at any time. Her blood was found to be group O Rh-positive (R,R₁), the child's group A Rh-positive (R,R₁): there could be no Rh incompatibility in this case. The maternal iso-agglutinin titres were: anti-A, 1:10,000; anti-B, 1:80. The infant's saliva reduced these titres to 1:128 and 1:32 respectively—evidence that he is a "secretor."

In three days the jaundice was disappearing, the haemoglobin had risen to 135%, and erythroblasts had almost entirely gone from the peripheral blood. To date the infant remains healthy.

The placenta was healthy and the mother's Wassermann reaction was negative. In view of the abnormally high anti-A agglutinin titre in the mother's serum this case may have been a mild type of erythroblastosis foetalis, such as has been described by Polayes and Ohlbaum (1945), who report nine cases of erythroblastosis foetalis in which the Rh factor was excluded as a possible immunizing agent. All of the children were group A and their mother group O, with high anti-A agglutinin titres in the mother's sera. With the exception of two cases which terminated fatally, the affected children in this group suffer from a relatively mild form of haemolytic anaemia of the newborn.

In connexion with this, should the affected infant require blood transfusion it would probably be advisable to use group O blood instead of group A, as anti-A agglutinin may be present. In this respect transfusion therapy is analogous to that used in cases where an Rh-positive affected infant is transfused with Rh-negative blood.

We are indebted to Dr. Joyce Rounthwaite, Elsie Inglis Maternity Hospital, for sending us the samples of blood and saliva.

Reviews

D.D.T.

DDT. The Synthetic Insecticide. By T. F. West, M.Sc., Ph.D., and G. A. Campbell, M.Sc. (Pp. 301; illustrated. 21s.) London: Chapman and Hall, 1946.

The discovery of the insecticidal properties of D.D.T. was made in Switzerland just before the recent war, and the information reached the allied nations at the end of 1942. In the comparatively short intervening time there has been such a concentration of work on the subject that nearly 300 names appear in the author index of this book, many of them relating to several publications. The volume is, in fact, a summary of the results of research on D.D.T. up to the end of 1945. Further data are, of course, continually appearing; but enough has been accumulated to produce a very useful reference book and bibliography for the worker in applied entomology. Its scope and layout can be indicated by the list of contents, which includes the following chapters: History and development, the basic researches, manufacture and chemistry, principles of formulation, toxic manifestations, D.D.T. in paints, etc., D.D.T. in textiles and paper, D.D.T. miscellany, D.D.T. against lice, D.D.T. against mosquitoes, D.D.T. against household pests, D.D.T. against other pests of man and animals, D.D.T. against plant pests, miscellaneous uses, effects of D.D.T. on beneficial insects, and phytotoxicity. This arrangement is convenient, although there are two "miscellaneous" chapters which make for redundancy or lack of sequence, so that a note on "D.D.T. dispersed as a fog" is 274 pages away from the "use of D.D.T. in aerosols." Also, the various species included in such chapters as the one on plant pests are given in alphabetical order of the common names. Surely it would be more interesting scientifically to group them biologically? Despite a perceptible favourable bias towards D.D.T., the authors have reviewed the results of trials very fairly. Perhaps the most questionable chapter is the one dealing with paints containing D.D.T. The authors give results of their own tests, hitherto unpublished, without comparable results from D.D.T. applied as a superficial spray. The latter is generally believed to be more efficient, and the important question as to the residual toxicity of the two methods is still not determined.

EVERYDAY PSYCHIATRY

Everyday Psychiatry. By John D. Campbell, M.D. (Pp. 333. 36s.) London: J. B. Lippincott Company.

The author of this book has had a wide experience of medical work, including general practice, and finally in the American Navy. Impressed with the very great importance of psychiatry for medicine, and especially with the large number of borderline patients who ask the advice of their family doctors, he seeks in this volume to do something to elucidate the problems presented by these patients for the general physician and surgeon, but especially for the general practitioner. While paying full tribute to the great advances achieved in this field by modern medical psychology and psychotherapy, he is by no means a convinced environmentalist, and regards the innate constitution as playing a very large part in the aetiology of all the cases presenting themselves, including the psychoneuroses. For this reason the book under review is valuable inasmuch as it presents a point of view which has perhaps been neglected in modern psychiatric literature. The main feature of his advocacy is, however, that scarcely any branch of medicine and surgery can be neglected when considering the treatment of these patients. Thus in discussing psychoneurosis he says:

"The treatment of psychoneurosis, therefore, is one of the most challenging problems in medicine. It requires the skill of the experienced examiner, the tact of the sympathetic listener, the insight of the psycho-analytic student, the ingenuity of the physiologist, the erudition of the literary scholar, and the human understanding of the general practitioner. Since psychoneurosis involves cortical activities, autonomic function, and all the personality factors, its treatment necessitates knowledge of life and all its vicissitudes. It is sincerely hoped that the day of pure psychotherapy has ended, and that the psychoneurotic patient may be considered as an individual with a sensitive cortex and a hyperactive autonomic nervous system, and not as an interesting case with many unconscious mechanisms."

Dr. Campbell points out the value of the sympathetic companionship of the family doctor with a patient coming through a depression, perhaps the only valuable treatment until the

biochemical secrets which undoubtedly underlie the condition are elucidated. His descriptive method is to classify patients into personality types, and as a whole this method seems to be profitable; but perhaps he takes it too far in trying to differentiate too clearly a homosexual type, who, he says, is the very opposite to the psychoneurotic type and almost never suffers from bodily somatic complaints and is emotionally quite stable—few would agree wholeheartedly with such a statement. He thinks that just as there are special schools for mental defectives so there should be special schools for schizoid children, since this will allow these solitary thinkers to be of most benefit to the world, and that any attempt to socialize them by mixing with normal children is futile. The chapter on chronic alcoholism is excellent, and the final chapters on personality examination and rehabilitation are well worthy of study.

This book may therefore be read with profit by all doctors, inasmuch as it presents clearly a useful point of view rather different from that of the usual run of books on medical psychology.

PARASITES AND PARASITIC DISEASES OF MAN

Enfermedades Parasitarias del Hombre y Parásitos de Interés Médico. By Dr. Rodolfo V. Talice, in the Faculty of Medicine, Montevideo. Vol. I. (Pp. 778; 189 figures and 3 coloured plates. No price given.) Published by Editorial Científica del Sindicato Médico del Uruguay.

In his preface to this first volume of his treatise on the parasites and parasitic diseases of man Prof. Talice discusses his reasons for writing it. He expresses the opinion that the excellent and very useful textbooks on parasitology which have been written in various languages all deal much more fully with the parasites than with the diseases they cause, so that the practical medical man may find it difficult, unless he has special knowledge, to read them. He also considers that works on pathology and clinical medicine which deal with parasitic diseases are written without sufficient biological knowledge, and that the abundant and valuable North and South American literature on these diseases is insufficiently known, both in the Americas and elsewhere. These judgments, if they could be admitted, would certainly justify the considerable task which Prof. Talice has undertaken. But can they be admitted? If the Latin-American doctor finds it difficult to read such books as Manson-Bahr's editions of *Manson's Tropical Diseases*, Strong's editions of Stitt's *Tropical Diseases*, Craig and Faust's *Clinical Parasitology*, and Brumpt's *Précis de Parasitologie*, it can hardly be because these books require too much special knowledge or are clinically inadequate. Nor can it be agreed that North and South American literature on parasitic diseases is insufficiently appreciated outside the Americas, for it is constantly being summarized and critically appraised by experts in the pages of the *Tropical Diseases Bulletin* and similar journals printed in English. It is valuable, nevertheless, to have in this volume the fruits of Prof. Talice's wide experience. His book is not likely to supplant any of those just mentioned, but its text, at any rate, may well prove to be a valuable supplement to them. This first volume deals with only the protozoa and the spirochaetes and the diseases they cause, the Rickettsias being excluded because they are not protozoa. Some experts will insist that the spirochaetes also are not protozoa, but Prof. Talice decides that they are, and a consideration of the diseases which they cause alongside those caused by the protozoa has certain clinical advantages.

It is impossible in the space available to comment upon the whole of a book of this size. It contains so much that there are bound to be some statements with which some experts will not agree. Its five parts deal respectively with the protozoa and protozoal diseases in general, amoebiasis, the flagellates and the diseases which they cause, balantidiosis, and the spirochaetoses (including syphilis and its allied diseases and the leptospiroses). Under each heading there is a complete account of the aetiology, epidemiology, pathology, symptoms, treatment, and prophylaxis of each disease, together with the laboratory and other methods of diagnosis. The reader thus gets a complete clinical picture of each disease and a description of the parasite which causes it. The author gives especially detailed consideration to treatment, and in the epidemiological sections he records Latin-American work as a basis for regional studies and prophylaxis. The results of some work done during the recent war were doubtless not available when the book was written. There is no mention, for example, of the Russian

work on cutaneous leishmaniasis published since 1941 and admirably reviewed by Dr. C. A. Hoare in the *Tropical Diseases Bulletin* (1944, 41, 331), which establishes, among other important results, the fact that cutaneous leishmaniasis is a disease of gerbils and soughs in Middle Asia and is maintained in them, and also transmitted to man, by the sandflies which share their burrows. This work should be included in future editions, even though it means the abandonment of the priority given to parasitic diseases which occur in the Americas.

A few other criticisms need to be made, even in a brief review. It is doubtful whether the reader will really be helped by the particular typographical variations chosen by the author to emphasize the various aspects of each disease. More serious is the fact that the illustrations, especially the reproductions of the photomicrographs of the parasites concerned, compare unfavourably with those given in the textbooks mentioned above. Some of them, indeed, will mislead the inexperienced clinician or laboratory worker, who will get truer guidance from the line drawings wherever these are given. The author has chosen to record his bibliography in the form of footnotes, so that reference to the papers quoted is not easy, while some of the reference numbers in the text apply to more than one paper. And there is no index. An index to a work of this calibre is so important that most readers will hope that future editions of this first volume and also the first editions of any succeeding volumes will contain an index to the whole work. The most useful practice is that adopted by Strong's editions of Stitt's *Tropical Diseases*, each volume of which contains an index to the whole work.

Notes on Books

A book on the biochemistry and therapeutics of iron has been written by three Swedish physicians, Drs. C. G. HOLMBERG, Bo VAHLQUIST, and JAN WALDENSTRÖM, under the title *Om Järn Och Järnterapi*. It consists of five chapters. The review copy comes from Malmö and can be seen in the library of the British Medical Association by members who have a working knowledge of the Swedish language.

Mr. HAMILTON BAILEY's *Demonstrations of Physical Signs in Clinical Surgery* began its long career in 1927 and has now passed through seven reprintings and appears this year in a tenth edition. With each succeeding edition the author has striven to improve his work, and the text has been thoroughly overhauled. Pictures, both plain and coloured, remain a large feature of the book; they now number 573, and Mr. Hamilton Bailey pays just tribute to his publishers, Messrs. John Wright and Sons, of Bristol, for their skill in correlating the illustrations with the text. The price of the volume is now 30s.

Preparations and Appliances

A RETRACTOR FOR VARICOSE VEIN SURGERY

Mr. R. ROWDEN FOOTE (London, W.1), writes:

The instrument illustrated is a modification of a self-retaining retractor used in other branches of surgery. The main points to be noted in this retractor, however, are as follows:

(1) It is so designed that the instrument does not get in the way of the surgeon. The angle of the shaft is adjusted so that the retractor lies flat on either side of the wound.

(2) The jaws of the retractor give a firm grip on the tissues, allowing them to be lifted without slip.

(3) The points of the teeth are so made that injury to neighbouring vessels may be avoided.

This retractor has been specially made for me by Mr. T. M. Proudfoot, M.B.E., of Messrs. Bell and Croyden, Wigmore Street, London, W.1.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JULY 27 1946

IMMUNIZATION WITH B.C.G.

In an issue of this *Journal* late in 1943 a good deal of space was given to reporting a meeting of the Tuberculosis Association and to editorial comment upon it (Dec. 4, 1943, p. 716, 722). The subject discussed was the use of B.C.G. vaccine for immunization against tuberculosis, and of the two principal speakers two came from Norway, one from Canada, and one from the U.S.A. The meeting concluded by passing a resolution in these terms: "The Council of the Tuberculosis Association is instructed to approach the Joint Tuberculosis Council and the Council of the National Association for the Prevention of Tuberculosis with a view to a joint request to the Minister of Health to make B.C.G. available for trial in this country." This resolution has now borne fruit: these three organizations appointed a joint committee to examine the question further, and the ultimate result was a deputation which went to the Ministry of Health last week. Sir Wilson Jameson received the deputation with sympathy and expressed himself willing to take steps to see if a suitable vaccine could be made available in this country. It would be necessary to appoint an expert committee to examine the use to which it could be put and the class of persons to be vaccinated. The whole question could be explored by the Ministry of Health.

The deputation presented a memorandum prepared by Prof. W. H. Tytler on behalf of the Joint Committee which gives a full account of the history and achievements of B.C.G. vaccine, and urges that official action should be taken to enable the vaccine to be used in this country. It

is to be hoped that this memorandum has been, or will be, printed in sufficient numbers for a considerable circulation as well as for its immediate purpose. It is an admirable statement, fair, complete, and thoroughly documented, and presents an overwhelming case. The story of B.C.G. may be retold briefly as follows: It is a tubercle bacillus of ovine origin originally found in 1908 by Calmette and Guérin to have lost its virulence after successive transfers on a bile-potato medium. Since then it has remained incapable of producing progressive disease even in the highly susceptible guinea-pig, and although there is a theoretical possibility of restoration of virulence, the danger of any such change during proper maintenance is highly remote. Although practically non-pathogenic, this organism, when administered in the form of a living vaccine, induces tuberculin sensitiveness and increases resistance to subsequent infection with virulent tubercle bacilli. It is unquestionably more effective in this direction than an ordinary heat-killed vaccine. It may perhaps be less effective than a living vaccine of Wells's vole bacillus, but that is another and more recent story. The immunizing effect of B.C.G. has been exhaustively studied in animals, and is the subject of

a long-term field trial in cattle which has now been in progress in this country for a number of years.

B.C.G. began to be used for human vaccination more than twenty years ago, and the first method employed by Calmette himself and his colleagues was administration by the mouth to infants within a few days of birth. Although this treatment was used for very large numbers of infants born into tuberculous families, with what were said to be promising results, it was abandoned within a few years in favour of subcutaneous injection: this proceeding was much more regularly followed by the development of tuberculin sensitiveness. Not long after these studies began in France the method was introduced in Norway, where the classical studies of Heimbeck and Wallgren have provided the soundest evidence we have of what B.C.G. can do. This consists largely of observations made in hospital nurses, who form a particularly suitable group for such study, and at the same time constitute a class in much greater need of protection against tuberculosis than the population as a whole. These nurses were Mantoux-tested on entry, and it had been observed that those who were negative more often developed tuberculosis during their training than those who were originally positive. Immunization of negative reactors with B.C.G. reduced the morbidity in one series from 17.6 to 2.6%. Similar effects were observed in medical students; and during recent years, in spite of the German occupation, other classes have been included, the ultimate object being to treat the whole of the tuberculin-negative population. One of the drawbacks of the method has recently been overcome: an abscess is fairly often produced by the subcutaneous injection of B.C.G., but the method of multiple puncture of skin to which the vaccine has been applied results in a trivial papular lesion leaving no scar, and appears also to be more effective than either subcutaneous or intracutaneous injection.

By no means all the results obtained with B.C.G. have been as conclusive as those in Scandinavia. There is still room for argument about the degree and duration of immunity, and the indications for using the method at all. But it is unquestionable that this is a method of increasing resistance to tuberculous infection which may be valuable in certain circumstances, and it is much to our discredit that this country has contributed nothing to its study in the human field. The submissions in this memorandum are that the method is safe, has a considerable degree of efficacy, and is relieved of one of its main drawbacks if the multiple puncture or scarification technique is used; further, "that there exists in the Tuberculosis Services of Great Britain, and among the medical profession generally, an active and widespread desire that a reliable supply of B.C.G. vaccine should be available here, as it has been for years in most other countries of the world." It is then pointed out that a single source of supply is highly desirable, and "that the product should have behind it some form of official backing: either preparation under direct auspices of a Government Department, such as the Ministry, or the Medical Research Council, or some form of guarantee or certification of the technical methods employed, provided by an official department such as the Standards Department of the Medical Research Council." The necessity for these

provisions is obvious: a uniform, safe, and active product is essential, and its manufacture should be as much a Government responsibility as that of smallpox vaccine lymph. The stringent precautions required in manufacture are detailed: since the vaccine is living neither heat nor antiseptics can be used; and since it must be used within ten days of preparation tests of pathogenicity cannot yield their results until later. These are required to show not only that no virulent bacilli are included, but that the bacillus has not undergone a further stage of degradation, resulting in failure to produce even a local lesion in the guinea-pig, and probably therefore in loss of immunizing power. The case for centralizing production under authority seems unanswerable. It seems a necessary corollary to official recognition that B.C.G. vaccination is worthy of adoption in this country, whether as a recognized method of immunization or for the purpose of further trial.

THE E.E.G. APPARATUS

Since the days of Galvani and Volta progress in electrophysiology has depended upon advances in electrical technique. For over a century the recording of the rapidly fluctuating minute potentials in living tissue necessitated the most sensitive devices. No amplification was available. The early mirror galvanometer, having too great inertia, gave place to the capillary electrometer, and that in turn to Einthoven's instrument. With each advance the sensitivity of the recording instrument was maintained while the inertia decreased, thus enabling the rapid changes of electrical potential to be followed more accurately. With the advent of the thermionic valve an instrument became available capable of detecting electrical fluctuations as small as two millionths of a volt and of following them faithfully. Even more important is the immense power of amplification possible, so that the sensitivity of the recording instrument is no longer so important. For very rapid electrical changes the cathode-ray oscillograph, with its inertia-less electron-beam, is an ideal recorder, but permanent records entail rather costly photography. For clinical electro-encephalography (E.E.G.) a permanent trace is needed, and, since the spontaneous rhythms of the brain are for the most part relatively slow, an inertia-less recorder is not essential. An electromagnetic oscillograph writing an ink trace on moving paper has become the accepted technique for clinical purposes.

These great technical advances might lead us to suppose that the detecting and recording problems of the electrophysiologist were at an end. But certain inherent difficulties remain. Just as the microscope cannot be used to observe at the same moment the very small and the very large, so there are difficulties in the way of recording accurately the slowest and fastest brain rhythms with the same amplifier conditions. For accuracy one or other must suffer. The range of frequencies so far studied in the human electro-encephalogram (E.E.G.) varies from 1/2 to 35 c/sec, but there are undoubtedly transients with a much faster frequency. It is fortunately possible to devise amplifiers and ink-writing instruments which give linear recording up to 60-70 c/sec. In this way the output is a faithful repro-

duction of the input, but the manufacture of good apparatus capable of maintaining this standard is apparently not easy. During the war clinical electro-encephalography was carried out in this country at fewer than a dozen centres, an American apparatus being used for the most part. This has proved itself to be generally reliable, but since it has been built only through the enterprise of its designer no large-scale manufacture has resulted. In any event, individual workers in England have shown that it is possible to construct apparatus as good, if not better. With the return of peace, clinical electro-encephalography will undoubtedly develop, and new departments will be established all over the country. The supply of suitable apparatus will become an acute problem. Gibbs and Lennox¹ drew attention to this difficulty in 1944. Max and his colleagues² expressed their anxiety at the poor performance of badly designed apparatus in the U.S.A. There is no doubt that inferior apparatus will yield inaccurate results and encourage dangerous fallacies. In the anticipation that British manufacturers would undertake the production of equipment, the Electro-encephalographic Society requested the preparation of recommendations for the design and performance of apparatus. These recommendations, accepted by the Ministry of Health as a basis for the development of equipment to be used in hospitals and clinics, have now been published by Dawson and Grey Walter.³ The authors emphasize that the performance recommended is not an unattained ideal, since such apparatus, both amateur and commercial, has been in existence for some time. Even the most inferior equipment will produce results of a sort, so that the unwary may be deceived by the external glitter and polish into the uncritical acceptance of poor performance. Indeed, only a thoroughly critical approach on the part of intending users of such apparatus will discourage the production of inferior and untrustworthy instruments. It is necessary to know not only what the apparatus *should* do but what it will not do and what it can do when it goes wrong. The warning implicit in this paper is clear, and intending users of E.E.G. apparatus should satisfy themselves that the performance fulfils these criteria.

In few branches of medicine are the results so easy to obtain and so easy to misinterpret as in the field of applied electrophysiology. Hitherto rapid advances in knowledge have been made by physiologists. Physiological "neurography" has become an established technique of neuro-anatomy; the limits set by histological methods for the identification of neural connexions have been overcome, and the existence of functional relationships within the brain become a matter of observation rather than speculation. Now, with the development of methods of automatic frequency analysis,⁴ the vastly complex E.E.G. data related to clinical problems of all sorts can be tackled. Dawson and Grey Walter⁵ have discussed the scope and limitations of the visual and the automatic methods of analysis. It is clear that initially automatic analysis will neither substantiate what is already partly known nor provide ready answers to what is unknown. Visual analysis selects the

obvious and makes it the familiar, whereas the automatic method makes no such human distinctions. By increasing the data about which nothing is known because it has been ignored, the issues for electro-encephalography will, no doubt for some time, be clouded rather than clarified by this new method. Certainly clinical work will at first be made no easier by it.

If it is necessary to urge upon designers and manufacturers the desirability of a thorough understanding of what is asked of them, it is equally important for clinicians and others entering this field to acquaint themselves with the instruments which technology can place in their hands. Only a critical approach by all concerned can prevent the development of an inferior practice and faulty theory so damaging as to retard electro-encephalography for years.

MENIERE'S DISEASE AND ALLERGY

Quincke suggested in 1893¹ that Ménière's disease might be due to an angioneurotic-oedema-like involvement of the internal ear or its nerve supply. In 1923 Duke² pointed out that Ménière's syndrome might be due to allergy, and recorded two cases in which attacks eased after withdrawal of the causative foods and were reproduced by their re-addition. Since then further cases sensitive either to foods or to inhalants have come to light. The total number over about a quarter of a century is no more than twenty, some of which are true cases of Ménière's disease, while others are doubtful. Thus, allergic reactions of the antigen-antibody type must be considered as only exceptional causes of the syndrome.

Williams³ has now put forward a new suggestion: that Ménière's disease (he prefers to call it endolymphatic hydrops) is the result of physical—or intrinsic—allergy. The term physical (intrinsic) allergy, also first introduced by Duke,⁴ implies that the stimulus of physical agents, such as heat, light, cold, and trauma, or even psychological disturbances, may produce symptoms identical with those of the antigen-antibody type of allergy. Williams emphasizes that the findings at necropsy in all the fourteen cases which have been described show that the unvarying pathological picture is one of a non-inflammatory distension of the endolymphatic system. From the intermittent nature of the illness it is clear that the pressures within the labyrinth must fluctuate. It would be difficult to conceive of such a fluctuating extracellular oedema having anything other than an allergic aetiology. Granted that two distinct physiological mechanisms may express themselves clinically in the same way, then the difficulties which have hitherto stood in the way of accepting this disease as a type of allergy seem to be resolved, according to Williams. The mechanism by which Ménière's disease is precipitated is as follows: a physical or emotional stimulus acting through the parasympathetic nervous system affects certain cells which have an inherited tendency to react in an abnormal manner. These cells are disrupted, with the release of histamine, a change in the permeability of the cell membranes, and an alteration of water and electrolyte metabolism. He cites Muller's work as the basis of his belief that the inherited tendency to physical allergy consists in a predisposition to the development of an abnormal capillary structure and function under certain stresses. Nicotinic acid is a vasodilating substance, which presumably acts by

releasing the contracted "lock muscle" at the beginning of the capillary loop, and its use in treatment is in keeping with this concept. The dose is 25 mg., increasing to usually 100 mg. daily, by hypodermic injection. This is continued for a month or more, when an attempt is made to change to oral therapy—100 mg. night and morning. Fluid is restricted to six glasses of water a day, and 6 g. of potassium nitrate are taken in divided doses with meals.

More recently, Williams⁵ has linked together Ménière's disease, vasomotor rhinitis, myalgia, and the vasodilating pain syndrome, including all four as the syndrome of physical allergy of the head. It is not advisable to define the word allergy too rigidly in the present state of our knowledge of clinical medicine, but at the same time care must be taken that it does not become a cloak for conditions that are but poorly understood.

THE BRAIN IN URAEMIA

Neurological study of cases of uraemia produces much which is of interest. The clinical pictures are diverse and include manifestations which can be related to all levels of the neuraxis, and features which have at times been regarded as due both to depression and to exaltation of function. A large literature has arisen on the question of the histopathological changes in the brain in fatal cases of uraemia. J. Knutson and A. B. Baker⁶ have done a service in combining a description of their findings of five cases with a summary of the earlier contributions on the subject. In the acute cases the nervous system may reveal but little naked-eye abnormality. Microscopically, however, there occurs swelling of neurones with greater or less degree of chromatolysis and with loss of staining properties. There is no characteristic distribution, and in the less severe cases diseased cells may be found lying among others which are normal in appearance. Where the uraemia has been more intense or prolonged the cell destruction occurs over wider areas, and the Purkinje cells of the cerebellum are particularly affected. Vascular congestion, perivascular infiltration, and petechiae may be found throughout the grey and white matter. In subacute cases (where the illness has lasted a matter of weeks or months) the nerve-cell changes are more variable in character and more widespread in distribution. Both acute and chronic changes can be detected. Focal and perivascular demyelination is prominent, especially in the white substance. Necrotic foci, sometimes actual cavitation, may be revealed. Vascular reaction is less intense, and there may be a mild glial increase, especially around the regions of necrosis. With chronic cases, where the illness has lasted many months or years, the lesions are parenchymal rather than neuronal. Pyknosis, shrinkage, and even disappearance of nerve cells may be detected, especially in the cerebellum and brain-stem. Both tissue-necroses and demyelination are pronounced, and small cavities may occur with thick glial surroundings. Vascular changes are not seen.

Perhaps the most interesting and difficult problem is that of pathogenesis. The interesting hypothesis of P. von Monakow⁷ is quoted. Struck by the sudden onset of cerebral symptoms in uraemia, the toxic and humoral features remaining unaltered, he concluded that there must have taken place some abrupt failure of a mechanism which had hitherto been protecting the nervous system from circulating poisons. This barrier, he believed, resided in the choroid plexus, which was capable of putting up for a long time a successful resistance.

The nature of the circulating poison in cases of uraemia remains a matter of debate. Whether or not a phenol is responsible for the cerebral symptoms in uraemia⁸⁻¹⁰ or alterations in the blood potassium level¹¹ is not yet known.

HOUSING IN THE TROPICS

Two interesting papers published by the University of Queensland deal with housing in tropical and subtropical regions. Prof. D. H. K. Lee¹² sets out the physiological principles which should be taken into account in designing dwellings for hot climates, and Langer¹³ deals with house construction and town planning.

A stable body temperature can be maintained even in very warm surroundings, but Lee remarks that this heat-regulation is not achieved without cost. The strain imposed on the circulatory and nervous systems, and on the digestive tract, is such that the margins of safety are reduced, so that other deleterious influences may more readily gain an ascendancy. Asthenia and laxity are common among dwellers in the Tropics, and they result from a combination of prolonged work, bad surroundings, and anxiety or malnutrition with exposure to heat. Mental instability and chronic neurasthenia are said to be due to heat and either too much or too little work combined with bad social conditions. In very hot environments the capacity for work is reduced, but the output of steady labour declines, as a defensive reaction, before the maximum capacity for work is affected. Of prime importance in the design of houses for regions such as Queensland is protection from solar radiation. The shade afforded by trees should be utilized so far as possible. Clearly, the best protection is obtained when the sun's rays are prevented from reaching the roof. Roofs made of bright metal, or treated with metallic paints, whitewash, or light-coloured paints reflect much of the incident radiation. Well-insulated roofs and walls are desirable, and ventilated cavities greatly reduce heat transmission through the structure. Windows should be restricted to aspects little exposed to the sun. Cooking appliances should be designed and arranged so that there is no avoidable "wild" heat. Air-conditioning should relieve the burden of heat during the hottest periods and provide comfortable resting conditions. When nights are hot enough to interfere with sleep, the cooling of sleeping quarters is of great importance.

Langer, in his outline of the essentials of a subtropical house, advocates three main methods of reducing heat indoors: cooling the walls with overhangs, ventilating the roof space as well as the rooms below, and the proper orientation of the house. Overhanging roofs can do much to protect walls from the sun's rays. Ventilation of the roof space by adjustable louvres is recommended, and where enough water is available pitched roofs can be further cooled by the provision of perforated water-pipes for spraying the roof surfaces. While adequate ventilation of rooms is necessary, protection is needed not only from cold winds in winter but also from the hot winds of summer. Large windows, allowing really good natural lighting, are favoured. They are productive of less direct glare than is experienced when windows are smaller and the general level of illumination less. Screens of vegetation can be used to protect windows from indirect glare. The strain imposed on the housewife by the tropical climate

is aggravated by the lack of domestic help, and Langer lays emphasis on the need for planning so as to reduce the burden of housework. The kitchen should overlook the children's play area, thus making supervision easier. Stairs cause much strain on the housewife, and on that score single-story houses are to be preferred. Labour-saving principles should be extended to town planning. Shops and other communal amenities should be not more than ten minutes' walk from any house. Opportunities for outdoor recreation are important, and ample provision should therefore be made for this in town-planning schemes.

ABSTRACTS OF WORLD MEDICINE

Under the above title the first issue of a new monthly abstracting journal will be published by the British Medical Association in January next year. A second monthly journal will appear at the same time under the title of *Abstracts of World Surgery, Obstetrics, and Gynaecology*. The work of these journals, and of other abstracting services, will be conducted under the general direction of the Editor of the *British Medical Journal*, and the Council of the Association has just appointed Dr. G. W. M. Findlay as Editor of *Abstracts*, and Dr. S. S. B. Gilder as Assistant Editor. Dr. Findlay, who comes to this new appointment from the Wellcome Research Institution, is well known for his researches on tropical infections, and is author of *Recent Advances in Chemotherapy*. Dr. Gilder, who as a prisoner-of-war in Germany had a varied surgical experience, brings to the abstracting service a useful knowledge of several foreign languages.

It is hoped to include within the scope of the two journals the principal medical periodicals published in different parts of the world. The service is international. The abstracts will be classified under headings, and will, for the most part, be "informative" in nature. That is to say, they will be full enough to give the reader a clear idea of the contents of the article abstracted. Careful selection of the articles to be abstracted will, it is believed, make the two new monthly journals a trustworthy guide through the maze of the multitudinous medical periodicals now coming off the world's printing presses. The journals will also contain shorter or "indicative" abstracts. In addition to the abstracting journals it is hoped to provide abstracting sections, or supplements, for specialist use. In the first instance these will be at the disposal of the Editors of the quarterly journals published by the B.M.A. It may be possible to extend this service to other specialist journals.

The abstracting journals will continue in an ampler form, made possible by peace, the work done by the *Bulletin of War Medicine* during the past five or six years. The *Bulletin* will cease publication next month, and we take this opportunity of paying a tribute to those who through its medium performed such a valuable service to Medicine during the war in exceptionally difficult circumstances.

Drs. E. G. Murphy and D. Swinscow have been appointed sub-editors on the staff of the *British Medical Journal*.

At a meeting of county medical officers of health, assistant county medical officers of health, and resident staffs of sanatoria held at University College, Dublin, on April 13, a society to be known as the Irish Tuberculosis Society was formed. Its object is the study of tuberculosis in Ireland in all its aspects, and for this purpose clinical meetings will be held at various centres. Ordinary membership is open to all registered medical practitioners. Applications for membership should be made to the honorary secretary, Irish Tuberculosis Society, The Hospital, Newcastle, Co. Wicklow. Annual subscription 10s. 6d.

PSYCHOLOGICAL REACTIONS IN WAR-BLINDED

BY

W. M. HARROWES, M.D.

Medical Director, New Soughton Hall Hospital; Honorary Consultant Psychiatrist to the Scottish National Institution for War-blinded

Loss of vision, it can hardly be disputed, is the most seriously disabling sensory deprivation that can befall human beings. In account of the very far-reaching individual reorganization which it calls for, it has always been a topic of such sympathetic interest as to warrant this brief review of 40 cases of war-blinded men.

At the Scottish National Institution for War-blinded, near Edinburgh, men who lost their sight in the war of 1939-45 undergo a "basic" training consisting of Braille reading, typing, horthand, woodwork, and basket-making—not as an end in themselves but as part of a reconstitutive process; the process, as it is called, of "learning how to be blind." While basic training is going on attempts are made to discover indications in each man for types of future occupation. The intention and programme is to reintegrate the blinded man into society as a functioning unit and to avoid segregation and over-protection.

The case material under review here has consisted, up to the present, of 40 men aged from 22 to 38, representing a wide range of occupations consisting of accountants, bakers, bricklayers, butchers, clerks, cooks, joiners, labourers, mechanics, miners, motor drivers, painters, plasterers, plumbers, policemen, quarrymen, roundsmen, saddlers, stokers, tramway conductors, and upholsterers.

As part of a general scrutiny of the patients, psychiatric examination was carried out in order that as full an understanding as possible might be gained of each man and his setting is a whole, and any possible resulting guidance obtained. The scheme followed was essentially along the lines of Adolf Meyer's personality study, and certain features were noticed with sufficient consistency to justify their mention as reactions to a special variety of trauma and as a contribution to the study of emotional responses generally.

Early Reaction to Loss of Vision

As a preliminary, each man was asked how he came to be disabled, and it was at once noted that definite and elaborate details were willingly supplied without any evidence that the recital caused distress of mind. Nor was this due to any defect in emotional facial play in the blind, as later became apparent.

It was then not difficult, without running an undue risk of wounding the subject's feelings, to insert a query as to the actual reaction to loss of vision. Here there was no definiteness of recall; the answers were vague, indifferent, and objective. Such replies were made as: "It got me down for a bit, but I got over it"; "There's no use crying about it"; "I knew I'd got it, and I could do nothing about it"; "It was just a case of my own guts." The most articulate and probably the most intelligent of the series, Case 40, with evident amusement said: "There was a week when I was like a bull in a china shop and fair mad, especially if anybody sympathized with me. Then it was all over, and I was only interested in overcoming it" (i.e., the handicap of total blindness). This man showed an overcompensatory reaction.

All the cases revealed in this way an apparent retrospective latching out of an emotion which must inevitably have been considerable, but this apparency was modified by further inquiry. Cases 3 and 20 spontaneously declared that at the time when they found they had lost their sight they wished they had been killed. This feeling persisted for, apparently, about eight to ten weeks. Cases 9, 10, 11, 13, 18, 26, 27, 28, 30, 33, and 40 all described a period of clear-cut distress of mind, hopelessness, misery, and sense of loss characterized by them as depression, for this was the word they used. They all wished to make it clear that this period of depression was over and that it had disappeared by a process of "wearing off." Only three of the men ascribed any specific benefit to any internal agency, and they said that association with other blinded men who were getting on well had "cheered them up."

One of the three, Case 30, subsequently falsified this. The remainder gave evidence of a similar reaction but of shorter duration. Whether the response had been marked, as in the first group, or less severe, as in the second, it was described quietly and objectively as a thing of the past. The calamitousness of loss of vision needs no emphasis—its implications seize the imagination with some force; and yet in the series the emotional reaction of depression seemed to have been the ordinary human response to loss or bereavement, failing completely to show any long-lasting characteristics of a true depressive reaction. Even the tragic predicament of blindness apparently did not here mobilize those deep instinctive mechanisms that produce psychopathological depression.

Such depression as was in fact reported by the men would seem to come under the heading of reactive "depressions, which are the direct reaction to circumscribed life situations. . . . [Reactive depressions] are usually of shorter duration than the more constitutionally determined type" (Diethelm, 1936).

All this, of course, was largely retrospective. The emotion under discussion was concerned with a static, finite entity, blindness, which had happened and was unmodifiable, and this seemed to be the attitude of the subjects. This, however, was in a proportion of the cases not an end-point, and as investigation proceeded three reaction types were seen rather clearly defined.

Late Reactions to Loss of Vision: (A) With Tension

This reaction made its appearance objectively and subjectively. Objectively, these subjects showed various behaviour disorders in connexion with the basic training, such as undue slowness in learning—possibly the expression of resistance, for no retardation was apparent—querulous fault-finding, uncooperativeness of various kinds, and insistence on the immediate finding of a future career or occupation with rejection of all suggestions.

Subjectively, there were complaints of various kinds quite consonant with the objective behaviour. In the interests of brevity and space, one typical case is quoted.

Case 21.—This patient was a man aged 38, formerly a cashier. He has no vision. Objectively, although an office worker, he was particularly slow at Braille typing and shorthand, and worked unwillingly at handicrafts. At an interview he described little shock over the actual loss of vision, but showed great concern about his future occupation. No suggestions for a career satisfied him, and he dismissed them all as "charity" or as jobs that a child could do. His facial expression was one of strain and worry. He said that he felt strung up and restless. He showed restlessness and irritability during interview. It was significant that the only suggestions he made for occupation were such things as could in fact be done only by a sighted person and involved a good deal of mobility.

Cases 3, 6, 7, 8, 9, 13, 20, 23, 28, 30, 32, 35, and 37 all showed similar reactions, with such additional symptoms as refusing occupation on the basis of a rationalized fear of failure, restlessness and discomfort when not moving about, "strung-upness," constant restlessness at interview, over-concern about unrelated and unimportant details of the life situation, nervousness, and poor sleep with relaxation only towards morning.

There was no association between the exhibition of these symptoms and the description of initial depression, as a glance at the case numbers will show. Nor, more important, could the symptoms be related to simple concern for the future, since Case 30, showing marked symptoms, was going back to an interesting post with his pre-war employers and with his pay and prospects unchanged. Attempts to relate the condition to personality traits were inconclusive.

This reaction is obviously one of tension, and as such is within the subjective life experience of almost everyone as a reaction to inevitably arising situations of frustration and indecision. Its chief interest is that it shares with anxiety some mobilization of vasovegetative mechanisms, but to a lesser degree and without the acuteness and "attack" of anxiety. To be noted also, probably, is the generally held view that anxiety, while reactive to some extent, really has to depend for its production on an inherent constitutional tendency towards special types of imagery connected with anticipation and a special type of vasovegetative responsiveness, and on the involvement of deep instinctive factors.

Security of the future played no real part in modifying the tension these cases showed; but emphasis was repeatedly laid by the subjects on mobility, and the inference seemed unavoidable that an important factor in the production of tension was the enforced relative immobility and helplessness of the sightless, which prevented it from being drafted off, as is so naturally done with the passing tensions of everyday life that are produced by transitory "impasse" or dilemma situations.

Watson's now classical demonstration of anger as the fundamental reaction to limitation of movement was interestingly illustrated. With the tension was seen, as is always the case, some angry irritability, and this found a peculiar target, for many of the men, in the persons of the one-eyed among their number. Towards these the sightless men showed jealousy and anger, and complained that they had no right to consideration—a new view of the proverb "In the country of the blind the one-eyed man is king."

As with the transitory and apparently non-pathologic depressive reaction to loss of vision, so also the later reactions in this group of 35% of the cases at first seem to consist of non-pathologic tension. It is striking, however, to read Muncie's (1934, 1939) description of tension depression, which might well have been specifically written of this group of cases: "In tension depression there are the outward manifestations of tension and, to a less obvious degree, of depression. Tension is expressed in a constant urge to restless strenuousness, chafing at restriction, and in an inability to submit to the collaboration necessary to therapy; a great demand for immediate results. . . . The unwary physician is in danger of minimizing the depression, to the patient's own detriment. . . . The reaction occurs in young adults who do not know how to adapt themselves to the exigencies of the difficult situation producing the reaction: commonly an unpleasant dilemma. . . . The reaction is likely to be prolonged."

These words, so accurately descriptive, show how, underneath an apparently rather everyday reaction to a grievous loss, there may well be a body of distress unclearly seen. Even Muncie's estimate of duration seems accurate. Case 21 lost his sight over four years ago and is still tense.

To sum up, the rather striking fact emerges that 35% of a group of 40 blinded men have developed a classical tension depression and that no other variety of depressive reaction was seen, thus showing the specificity of tension for certain types of situation and opening up again the question of reactivity generally.

(B) Overcompensation

Case 40 was the only clear-cut example of this. He was a man of high intelligence who was seen privately because he had cut himself off from any organization for the blind. He said he did not want to live in the country of the blind. He came carrying an ebony walking-stick in contempt of the white cane carried, very usefully, by sightless people. He caricatured, very accurately and cleverly, the posture and manner of blinded people and showed how differently he comported himself. He had gone, alone, to an engineering works, had been kindly received by the management, and had in front of them produced 50% of the maximum output on a precision lathe which he had never "seen" before. This was confirmed. He did at least one delicate assembly job better than a sighted worker could. He said that a major proportion, not a minor proportion, of jobs in an engineering shop could be done by sightless people. He declared he was just as safe as a sighted person at unguarded machinery—manifestly incorrect. He was active, pushing, driving, always on the move, full of plans and missionary ideas, and quite unable to understand that his abilities were far in excess of the average. The mood was stable; there was no suggestion of any morbid excitement. His whole personality was enthusiastically absorbed in defeating his handicap. One can only speculate as to how this reaction will go on.

(C) Re-stabilization

This group accounts for the remainder of the cases. It is impossible to convey adequately in words the marked difference in type of rapport experienced in talking to this section of the case material, due, of course, to the absence of tension and to the real re-stabilization. One typical example may suffice.

Case 5.—A single man of 32, by trade a baker, was totally blinded by a grenade in the action at Imphal in May, 1944. Unaided, he crawled away, was found, and was ultimately flown home. He said he knew at once that his sight was gone, and had to keep a grip of himself for "a little." The mood was stable, and the content of thought was a modestly depreciatory account of his slowness at the basic training, especially Braille. It was ascertained objectively later that he was in fact a persevering worker who was making good progress. He expressed great satisfaction with his surroundings, with the organization, and with the training. He said he knew his range of occupation depended on how well he mastered his training, which he was trying to do while awaiting developments.

This reaction of patient endeavour, the reaction of the majority of the cases, is evidently a true re-establishment of an emotional balance, and an example of how far personality reorganization can go. It seems to give a special meaning to that last line of blind John Milton, written on his blindness: "They also serve who only stand and wait."

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY

The annual general meeting of the London and Counties Medical Protection Society was held at Victory House, Leicester Square, on July 3. Sir Ernest Rock Carling, the president, said that the Society had had a successful year, with the election of over 1,000 new members. The secretary, Dr. R. W. Durand, had returned from service in the Royal Air Force, and, the work of the office having been reorganized, he was engaged in giving lectures at medical and dental schools, attending, at the instance of the council, court proceedings which might be of interest to the Society, and was also available for interviewing members who had complaints or difficulties. The joint committee representing the Society, together with the Medical Defence Union and the Medical and Dental Defence Union of Scotland, had worked out a number of recommendations for the reform of the General Medical Council, and these had already been submitted to that body (*Journal*, July 6, p. 21).

Sir Ernest Rock Carling went on to say that many people were wondering whether impending legislation, with the incorporation of medical men in a State service, would have any effect upon the work of a defence society. He could not believe that it would result in any diminution in the number of disputes likely to arise, and he felt quite sure that the number of complaints against medical men before regional boards and perhaps before the Ministry of Health would be considerable. On the occasion of this annual meeting it was customary for the president to remark on various defaults by some members of the profession which caused trouble to the Society, but he would mention only one—the frequent failure of medical men to keep records. Over and over again difficulties arose in cases which came to the Society's attention because complete and precise records had not been kept. A case unsupported by documentary evidence was very likely to go down under clever cross-examination.

The financial report, presented by Mr. W. M. Mollison, the treasurer, showed an excess of income over expenditure of nearly £6,000, and accumulated funds to the amount of £112,000.

The annual report, which was adopted at the meeting, was in its pre-war form and contained notes on some of the more important and interesting cases undertaken by the Society during the years 1939-45. It stated that the public is becoming increasingly litigious and tends to complain to the "authorities" regarding the work of practitioners, apart altogether from legal actions, more than it did before the war. An impression, the report said, exists among certain practitioners who are in the whole-time employment of local authorities or hospitals that there is no need for them to be members of a protection society because their employers will defend and indemnify them against any actions. This is a misapprehension, and there is even greater misapprehension on the part of those in the Forces that by reason of their service they are immune from legal process. The manual of law of each Service states quite clearly that an individual by reason of his service is neither deprived of his civil rights nor freed from his civil obligations, and those in the Services are liable to have actions brought against them on account of their professional work.

The officers and retiring members of Council were all re-elected.

AN OUTBREAK OF INFECTION DUE TO SALM. TYPHI-MURIUM

BY

F. E. CAMPS, M.D.

A view of the possibility of similar outbreaks of infection it is felt that a short preliminary description of this epidemic is justified at this stage, although the investigation is not yet complete in full detail.

On Thursday, July 4, three cases of acute gastro-enteritis were notified in the Witham Urban District. There were a further twelve cases on the Friday, and a large number of cases on the Saturday, Sunday, and Monday, giving the classical picture of an explosive outbreak.

Clinical Findings

The clinical picture of the disease was constant. Headache was a prominent early symptom, and pyrexia was also present. At the onset there was intermittent epigastric pain, associated with nausea or vomiting, and followed some two to three hours later by diarrhoea. This would last in severe cases for as long as three days or more, and be accompanied by prostration. In milder cases the pain might resemble that of a dyspepsia and be followed by a few loose bowel actions. The presence of blood was more common in children than in adults. In many of the mild cases a more severe recurrence appeared seven days after the primary symptoms.

Information was difficult to obtain in the early stages of the epidemic. Only the more severe cases were notified, while those patients with mild attacks were regarded as suffering from merely the usual upsets which are liable to occur at this time of the year. Many of those affected did not seek medical advice at all. A further complication lay in the fact that many practitioners did not know that such cases can be notified, and for these reasons the existence of an epidemic was not realized in some districts until it had been present for a considerable time. In Witham, however, its presence was rapidly appreciated, owing to the fact that all the local doctors are in partnership, and one of them is the acting Medical Officer of Health.

An analysis of all the available data as to food consumed by the infected persons showed the only common factor to be the meat supply. The slaughter-house distributing meat was in Witham itself, and this rendered the investigation considerably easier. The raw meat ration for the infected area and also tinned meat were supplied by this slaughter-house to the retail butchers.

Bacteriological Investigation

Bacteriological investigation of the faeces of those infected showed *Salmonella typhi-murium* in all specimens. Cases were soon identified among the employees of the retail meat distributors, and, as was to be expected, secondary cases rapidly arose from this source. Although the exact origin of the infection is still under investigation, certain possible sources of spread have been identified. Measures for the control of the epidemic have been based upon this data.

The tinned meat was found to be uninfected in the tins but to be infected in the butcher's shop. As the distribution was from a common source, the raw meat appears to have been the infectious agent. Raw meat, however, would be cooked before consumption, and although it is recognized that cooking does not always destroy this organism, it seems unlikely that inadequate cooking could have been the cause of so many cases. It seems more probable that the spread was due to contamination of the tinned meat, after opening, by the raw meat. This could have followed contact on the butcher's slabs, infection of the slabs themselves, infection of the knives, cleavers, and other cutting instruments, infection of the workers' hands, and contact in parcelling. It seems likely that all these factors played a part. At the same time, once the retail distributors became infected themselves they would be in a position to re-infect further cooked food.

Control therefore took the form of:

1. Removing any source of infection from the slaughter-house.
2. Cleaning of all slabs, containers, and knives in the retail establishments.
3. Tightening up generally the hygiene of food-handlers, with stress on the desirability of careful washing of the hands, particularly after using the w.c.
4. Circularization of all retailers on the importance of early recognition of symptoms among their workers, and of cessation of work by all doubtful cases or contacts.
5. A recommendation that cooked meat should be packed independently of raw meat.
6. Circularization of medical practitioners informing them about the epidemic, and about the measures being taken, together with a request for their co-operation, particularly with regard to notification.

As a result of these measures, the number of cases appears to have abated, although secondary cases may be expected to continue. Full appreciation should be recorded of the efforts of Dr. T. G. Benjamin and Dr. J. G. Denholme of Witham, and of the work done by Mr. E. Wadhams, the sanitary inspector. Dr. Ross Mackenzie, pathologist at the Essex County Hospital, Black Notley, was responsible for all the bacteriological investigations. Dr. W. A. Bullough, County Medical Officer of Health, placed the full resources of his department at our disposal.

Two Important Points

This outbreak of food-poisoning due to an organism of the *Salmonella* group involved a combination of circumstances the most important of which was the presence of the organism at a central point for food distribution during a spell of hot weather. Nevertheless, it once again draws attention to certain basic principles of hygiene.

Advice about washing the hands after using the w.c. is often repeated but rarely heeded. The risk of infection of cooked food by assistants in the distributing shops should be negligible if this elementary precaution is carried out; and this also applies to case-to-case infection in private houses.

Countless investigations have shown this route to be the source of infection in similar outbreaks. Yet it appears that the public still do not appreciate this very real danger. In some schools notices are posted on the lavatory doors reminding the users to wash their hands. If the public generally could be fully educated on this point, gastro-intestinal infections, which are becoming more and more prevalent, could be considerably curtailed.

Fortunately, up till now most of these outbreaks have been mild, from a clinical point of view, but this has led to the acceptance of attacks of diarrhoea as being quite an ordinary event. Patients fail to seek medical advice, and practitioners fail to notify such cases as they do come across. It is not generally realized that attacks of this kind associated with food are notifiable under the Food and Drugs Act. There is a real danger in this attitude of mind on the part of both patients and doctors. Once an outbreak is allowed to gain momentum it is almost impossible to control it, whereas if it is caught early it can often be cut short. It should be appreciated that all such outbreaks are not necessarily mild clinically, and an uncontrolled epidemic of a more serious nature might well be a major catastrophe.

The work of the Red Cross and St. John Hospital Library, which during the war distributed more than four million books to Service patients, has been reorganized for peace-time work as a department of St. John and Red Cross. It has now moved to new headquarters, 40, William IV Street, Trafalgar Square, W.C.2, and is extending and developing its activities in all Service hospitals, both at home and overseas, and in civilian hospitals, and kindred institutions in England, Wales, and Northern Ireland. While the hospital library department will continue to provide books by direct gift to form the nucleus of any new hospital library or to restock any existing one, a special feature will be the loan libraries. These will provide an individual service for patients requiring special technical, foreign, or books difficult to obtain. One of these technical libraries will be solely available for tuberculous patients in sanatoria, and the books will be kept in a room apart from other books and will go only to and from the sanatoria.

WORK OF THE LISTER INSTITUTE

Nutritive Value of Different Food Proteins

The report for 1946 of the Governing Body of the Lister Institute contains an account of some continued work by Dr. Harriette Chick and Mr. E. B. Slack at Cambridge on the growth-promoting value of wheat proteins for young rats. This work has been extended in view of the changes introduced in the percentage of wheat grain in national flour. A set of tests made with flours of respectively 70, 80, 85, and 100% extraction, milled from the same grist, confirm previous results in showing a progressive increase in growth-promoting value for young rats of the proteins of these flours. The analysis at the end of the trials showed that the proportion of ingested nitrogen finally incorporated in the animals' tissues was increased from 23% to 27% as the degree of extraction of flour was raised from 70% to 100%.

The superior nutritive value of whole-wheat-flour proteins over those in white flour led to the study of all the proteins in the outer coat of the grain, more especially in the aleurone layer, which, in ordinary milling, is separated with the bran and contains about 16% of the total protein of the grain. The nutritive value of a diet containing white flour as the protein source was compared with a similar diet in which one-fifth of this flour was replaced by bran. The result showed an advantage of about 25% in the utilization for growth of the nitrogen in the mixture containing bran, although the bran lowered the coefficient of its digestibility.

Work has also been carried out by the Institute on the milk substitutes used in infant feeding. Biological tests with newly weaned rats were made, at the request of U.N.R.R.A., on the nutritive value of the proteins in a series of "Maltavena" emergency baby foods, designed to replace milk where milk may be unobtainable or in short supply. The common ingredient is an extract of malted barley, which provides about one-third of the total nitrogen, the remaining two-thirds being derived from wheat flour and skim milk powder, and the total amount of protein so arranged as to be about equal to that in human milk. The proteins in foods containing wheat flour and skim milk powder (as well as in another food containing wheat flour and dried human serum) were much inferior in value to those of the milk in the standard diet, but those in a food containing soya flour had a value only very slightly inferior to that of milk proteins. This result is presumably due to the effect of the supplementary action of the proteins contained in the different foods (malt extract, wheat flour, soya flour) included. In addition, the soya preparations provided a useful amount of fat and an adequate supply of B vitamins. These milk-substitute baby foods would, however, need supplementing with vitamins A and D. A report is given on the work of the unit for the preparation of plasma and plasma products administered by the Medical Research Council on behalf of the Ministry of Health. The filtration of large pools of human plasma from hundreds of donors—the original method of operation—has been discontinued, and unfiltered plasma for transfusion is now distributed for drying from pools consisting of plasma from only ten donors. Experiments are in progress for determining the effect on liquid and dried plasma of storage under various conditions. Another investigation concerns the possibility of delaying the absorption of penicillin by incorporating it in fibrinogen products. The Army authorities have presented to the Institute, on long loan, the human-plasma drying-plant used by them during the war. Part of this plant is being erected for the purpose of drying human plasma for civilian needs.

Other studies which have been (or in most cases are being) undertaken by the staff of the Institute include the investigation of certain types of serum antibody described as incomplete, immature, or univalent; the distribution of lecithin in muscle, by separation of various fractions and determination of the lipid constituents; the morphological, and particularly the cytological, characters of the group of myxococci; the cardiac hypertrophy produced by arterio-venous anastomosis; the search for a test to detect the presence of pyrogens and other reacting substances in transfusion material; the chemical changes in ischaemic muscle; the isolation of the specific blood group O substance (antigenic when given intravenously to rabbits and inducing the formation of potent and useful anti-O sera which

have been employed in the examination of A, B and O erythrocytes); the breakdown of fibrinogen under the influence of serum protease; the mutual reaction of tetanus toxin and antitoxin, and many other studies in the fields of pathology, biochemistry, and biophysics. Much work has been done on nicotinamide and related compounds, including an investigation to decide which species of bacteria are most concerned with the nicotinamide supply by the intestinal flora of man, and how variation in diet and administration of drugs affect the composition of the flora as well as the urinary elimination of nicotinamide methochloride.

All members of the Institute staff, with two exceptions, have evacuated their wartime home at Cambridge and have returned to the Institute. The report, which is signed by Sir Henry Dale, the chairman of the Governing Body, records appreciation of the continued collaboration of the Institute with the Medical Research Council.

FUTURE OF THE KING'S FUND

The possible effect upon hospitals of the National Health Service Bill was the principal topic at the meeting of the general council of King Edward's Hospital Fund for London, held at St. James's Palace. The Speaker of the House of Commons, Col. Clifton Brown, presided. He pointed out that the King's Fund was not immediately affected by the Bill, but it was obvious that the Fund would have to take account of the vast changes impending in the hospital system. The fact that, after the appointed day, the Minister would assume responsibility for the ordinary expenditure of the hospitals would set free a large proportion of the income of the Fund for purposes other than those to which it had been for the most part devoted in the past. He reminded the meeting that the King's Fund had never been confined to financial support alone; it had always taken a deep interest in the efficiency of the hospital services, and the Act of 1907 by which it was governed was in wide terms, allowing for the expansion of activities in which the Fund even at that date was already engaged. It seemed clear that the way would be open to the Fund to use its resources to promote progress in all those many directions which lay outside the immediate purview of a State hospital service.

The effect of the Bill upon individual voluntary hospitals, said the Speaker, was regarded with anxiety, but some minds would be relieved by the Minister's declared intention to preserve a measure of freedom and independence throughout the new organization and also by the provision for hospital management committees to have free money to use for purposes outside the State-provided service. The hospital endowments fund, representing the common pool in which endowments and other funds now held by hospitals (other than teaching hospitals) would be put, was to be distributed to the various regional boards, and through them to the hospital management committees, and it was understood that those committees, which might control a number of hospitals in an area, would be able to accept and use gifts of money from outside sources. "This 'free' money will be of great importance to the hospitals as it will prevent the strangling effect of reliance on the State for the whole of the income, with the rules and regulations that must govern such expenditure, while it will still be possible for the public to express in concrete form their goodwill and confidence in the hospital services."

Coming events do not seem as yet to be reflected in financial deficiency. It was reported by the treasurer, Sir Edward Peacock, that the income of the Fund for 1945 had been well maintained. Excluding legacies, the general receipts were £324,095, over £20,000 more than in the previous year. General legacies amounted to £140,615, an increase of £90,000, and a further instalment of £75,000 was received from the Nuffield Trust for special areas. Ordinary distributions for 1945 amounted to £302,500, together with provision for two special grants of £10,000 each.

Reports were presented by Sir Ernest Rock Carling for the Radium Committee, which has maintained the services of the radium pool and the consultant panel of physicists; by Dr. Morley Fletcher for the Nursing Recruitment Committee, which has continued its policy of seeking to augment and assist the recruitment work of individual hospitals; by Sir Hugh Lee

the Diet Committee, and by Sir Harold Wernher for the emergency Bed Service Committee.

Sir Alfred Webb-Johnson, P.R.C.S., said that many had held the view that a change of ownership of hospitals was unnecessary in order to achieve an integrated hospital service for the nation; but if Parliament decided otherwise they must find their efforts to ensure that under a State service the atmosphere of freedom in which so much had been done for the advancement of medical science was preserved.

"We are fortunate in having a Minister of Health who, although determined to carry through bold and revolutionary changes, is ready and anxious to discuss the dangers of such proceedings and how to avoid them. He realizes that safeguards are necessary, and is undertaking to propose amendments on the report stage of the Bill which will give a greater measure of freedom to hospital management committees."

FOOD AND MATERNITY AND CHILD WELFARE

The annual general meeting of the National Baby Welfare Council, which was held at St. Pancras Town Hall on May 21, as addressed by Dr. Edith Summerskill, M.P., Parliamentary Secretary to the Ministry of Food, who announced that she was leaving for the United States next day as a delegate to the Food and Agricultural Committee, which was an offshoot of the United Nations Organization. She felt that this form of international social service on nutrition was essential.

Dr. Summerskill said that for twenty years she had been a practising doctor, and for twenty years she had prescribed medicine, sometimes even for babies, but she felt that her work now was in the field of social medicine. In taking on her post in the Ministry of Food she had made her special task the provision of adequate food supplies for children. Even in these difficult times babies would and could be adequately fed. Immense strides had been made in this respect since the earlier European war, and there had come about a general realization that in the past not enough attention had been paid to the proper feeding of children and expectant mothers, and that they must be better looked after in the future.

The Ministry of Food, which began as a purely wartime expedient, would now be permanent. While rationing continued, children's diet would need to be reinforced with milk and with vitamins as it was during the war, and the expectant mother must have additions to her basic food supply. It was a sad fact that before the war 30% of the babies in this country were bottle-fed, owing in a great measure to the mother getting up too soon and losing the milk. Therefore the care of nursing mothers was an important factor, as well as extra rations and queue priority. Family allowances (Dr. Summerskill continued) were to begin this year; also, from July 21 next, priority milk would be at 1½d. a pint instead of 2d., and cod-liver oil and orange juice would be at reduced prices. These two facts put this country in the forefront in baby welfare. Despite war conditions there had been no serious epidemics; the infant mortality rate had steadily dropped, and rickets, sometimes called the "English disease," was much reduced owing to the attention paid to maternal and infant dietetics. The education of mothers on the proper balancing of the diet was of the utmost necessity. She added that the extra milk scheme was entirely successful and on the whole it had not been abused. The way in which vitamins had been taken up was less encouraging.

In reply to questions from the audience Dr. Summerskill said that the provision of milk for school-children during holidays was a great administrative problem. It was not merely a question of delivering milk to the children's homes instead of to the schools, for it had to be remembered that a large number of children were away during the holidays and the distribution would be extremely complicated. Children who were at home had been invited to go to get the milk, but it was surprising in how few cases this had been done. It was possible that dried milk might be distributed to the parents. She added a word of sympathy with the teachers, who had so many additional duties thrust upon them in connexion with the service of food as to interfere with their teaching duties proper.

Lord Forrester, chairman of the council, said that he had lately visited many countries in Europe, as well as South Africa, Australia, and New Zealand, and he had found almost everywhere a new realization of responsibility towards children. He hoped that the National Baby Welfare Council would be able to send a mission of goodwill to Europe, with the offer of help, advice, and skilled assistance.

Dr. D. H. Geffen, chairman of the Executive Committee, in reporting on the year's work, said that the Council had restarted a series of competitions, one of which had been directed to ascertaining the views of housewives on housing. Exceedingly few women showed any desire for communal living, practically all preferring an individual home of their own.

EPSOM COLLEGE

At the 93rd annual general meeting of the Governors of Epsom College, held on July 5, Mr. Douglas C. Bartley, chairman of the Council, presided in the absence of the President, Lord Leverhulme, who was in America. He referred to the raising of the school fees, a matter over which the Council had taken a great deal of trouble before ultimately deciding to raise them as follows: Sons of medical men: £170 p.a. for boarders, £65 p.a. for day-boys; sons of registered dental surgeons: £175 p.a. for boarders, £70 p.a. for day-boys; other boys: £180 p.a. for boarders, £75 p.a. for day-boys. To show the spirit prevailing at Epsom between the parents and the College, he mentioned that though parents of boys already in the school were not legally bound to pay the increased fees, 90% of those parents agreed voluntarily to do so. Furthermore, out of the 10% who did not do so, 9% were parents who simply could not afford to pay the increased rate. In moving the adoption of the report, the Chairman referred to the loss sustained by the death of Mr. T. Hollis Walker, K.C., an Old Epsomian and vice-president, who served on the Council for 24 years, during which time his wide legal knowledge and experience had been freely placed at the service of the College. On the motion of Dr. Harold Spitta, vice-chairman of the Council, the Governors unanimously elected Surgeon Vice-Admiral Sir Reginald Bond, K.C.B., F.R.C.P., F.R.C.S., a Vice-President of the College as some slight token of gratitude for the valuable services he had rendered as Treasurer during the difficult war years.

Reports of Societies

PROGRESS IN UROLOGY

An address entitled "Urological Reflections" was given to the Section of Urology of the Royal Society of Medicine on June 27 by Sir HENRY WADE, of Edinburgh. In tracing the progress of urology during his own career he said that when he was a surgical youngster urology occupied a very humble seat at the banquet, but to-day it had a well-earned place at the high table. Methods of diagnosis in urology were now so exact, so perfect, that at the end of an examination the urologist did not express an opinion, he stated a fact, which almost invariably proved correct.

Many things accounted for this rise to pre-eminence: the physicist had given urology x rays; the chemist, pyelographic media; the biochemist had made excretion urography possible; the bacteriologist and the clinical pathologist had assisted in diagnosis and treatment. When he was a student the diagnostic methods were almost entirely clinical. In renal surgery diagnostic incision was considered justifiable, not only exposing the kidney but cutting its substance. One in three of the kidneys so exposed revealed no visible disease. In speaking of the introduction of new methods he expressed the view that excretion urography, a most valuable method in the hands of the skilled urologist, had on the whole done more harm than good, for, like a modern operation, its value must not be judged by the cases treated by the expert, but by the results in the hands of the common surgeon. "I suppose there is not one of us who has not seen this method of excretion urography used to delineate a renal tumour or similar disease, oblivious of the fact that the alleged deformity of the contour that is seen in the photograph is the result of the photographing of a running stream which varies from moment to moment like a Highland burn in spate."

The determination of renal function by the physician was most commonly made by carrying out a urea concentration test or similar method. In his own experience the simpler method of blood examination, in which the blood urea was estimated and the urea nitrogen or non-protein nitrogen and creatinine determined, had proved a most valuable diagnostic aid. A method, however, which he would put first of all, and which many younger urologists were liable to overlook, was the examination of the patient's tongue.

In speaking of treatment Sir Henry Wade gave some interesting recollections of his experience as a civil surgeon in the South African war and later as conservator of the museum of the Royal College of Surgeons of Edinburgh. For two years he was pathologist to the Royal Infirmary and carried out all the post-mortem examinations done on surgical cases. In certain of these the operation of prostatectomy had been done,

and he was interested to observe how frequently there was a pronounced degree of hydronephrosis, and how sometimes the renal secreting tissue was reduced to a thin membrane covering bags of water. He found on analysing 50 specimens presented to the museum as illustrating simple prostatic hypertrophy that 10%, unknown to the operator, were the site of carcinoma. If the case was one of simple hypertrophy the conditions were ideal for treatment by suprapubic enucleation, an operation which was then being popularized by Freyer, but in prostatic carcinoma or interstitial prostatitis an attempt at enucleation from above might be attended by serious consequences. At this period the mortality attending the operative treatment for prostatic enlargement was extremely high; even down to 1920 in one institution with which he had been associated it amounted to 25%.

Sir Henry Wade then went on to describe the work of Hugh Young, of Baltimore. When he went to the U.S.A. in 1920 the operation of transurethral prostatectomy was sweeping the country. He himself was drawn to the technique of perineal prostatectomy practised by Hugh Young in all cases of simple enlargement, but this again called for a special technique with special instruments, a very accurate anatomical knowledge, and a well-trained team. A technique very similar was employed by Young in his operation of total excision of the genital tract for tuberculous disease, in which the epididymis, vas deferens, seminal vesicles, and frequently a part of the prostate were removed in one piece.

Renal Tuberculosis

Turning to the role of surgery in renal tuberculosis, he said that it had been his lot to excise many tuberculous kidneys, but in almost all cases he had done this with an apology and a hope for a better treatment in the future. When he was a student and house surgeon hardly an operating day passed without joints being excised or bones resected for tuberculous disease, yet this treatment was now unknown, for it had been shown, by Sir Robert Jones especially, that a better result could be obtained, without mutilation, by conservative means. Why, then, should not a similar result be possible in renal surgery? The underlying process of natural healing was the same in both cases. In both the infection was combated and walled off and the debris conveyed to a free surface and there discharged and the sinus healed. But unfortunately the free surface in the kidney was the renal pelvis, and into it the debris containing tubercle bacilli was discharged to reinfect the kidney at some other part and to infect the ureter and bladder, the process of cure and reinfection continuing until the organ was completely destroyed. Meanwhile a systolic bladder had been produced which by its backward pressure ultimately destroyed the functioning tissue of the remaining kidney and led to death by uraemia. He had had several such cases and had tried various remedies, the most successful of which was transplantation of the remaining ureter into the pelvic colon. He hoped that the day was not far distant when nephrectomy in renal tuberculosis would be required no longer. If it was indicated, the surgeon was under an obligation to care for his patient for two years afterwards and to arrange sanatorium treatment.

Sir Henry Wade closed his address with some sombre reflections, as he called them, on the future of urology.

"My fear for you arises from the tools you have fashioned, the skill you have shown, and the dexterity you possess. Others may seek your aid, asking for your services as a technician, not as a physician. Be warned against this insidious evil. Never examine an organ or a region, examine only a patient. Remember that medicine is an art, not a science, and that you possess many an instrument to tell you when a man is ill, but none to tell you when he is well. Man is not a motor-car, susceptible to the methods of overhaul and repair of such a vehicle. Psychological derangements, particularly in the young female, may simulate actual organic disease. I recall one summer morning meeting in his consulting room in Boston Dr. Harvey Cushing, the father of neurosurgery. With a twinkle in his eye he told me that he had just seen a case sent to him as one of pituitary tumour, and it really was the case of an overworked stenographer who required a six weeks' holiday!"

It was important to bear in mind that the final conclusions at which the urologist arrived were not a diagnosis but a confirmed observation of the presence of an abnormality in the organ he had examined, and from the limited vision of the

specialist he might honestly believe it to be the cause of ill-health, while in fact the ill-health was due to something outside his knowledge. The answer to this was possibly the establishment of a polyclinic or health centre, where a whole-time staff would be available to carry out a complete investigation with all aids known and in all departments of medicine. Such a health centre might be an institution of the greatest value. On the other hand, a so-called diagnostic clinic might simply lead to procrastination and transform the educated clinician into a collector of chits. The majority of ailments of which mankind complained were incapable of exact scientific demonstration.

Correspondence

Demobilized Specialists

SIR,—Medical officers who have just been released from the Services where they had been trained, or were training, as specialists are finding difficulty in obtaining work in civilian life for which they are fitted, and their predicament has been causing us much concern. We are impressed not only by the individual hardship involved, but also by the fact that these men may be driven to abandon their plans for specialization at a time when there is a great dearth of specialists in every branch of medicine and surgery. In this fashion a reservoir of most useful recruits for the consultant service of the future will be lost.

The men concerned fall into two groups. Group I consists of about 800 men who were being trained as consultants, and have perhaps acted as graded specialists. They are about 28–33 years old, and they have either taken, or are preparing for, higher qualifications. They are now acting as registrars at teaching or other hospitals where they are paid £550 plus £100 for maintenance. We propose that their term of office should be extended, if they so desire, until the Bill comes into operation, provided that the postgraduate deans who selected them are satisfied with their work.

Group II is an older group of men who have been qualified perhaps for ten years or more, and some of whom are nearly 40 years of age. Nearly all of them have consultant qualifications. We ask the Ministry of Health to create for these men a number of more senior, salaried whole-time appointments. Since their appointments will occupy all their time, these men will not compete for private practice with the other unpaid assistant physicians and surgeons on the staff of the hospital. Hospitals would be asked how many posts of this kind they need, and the appointments would be made by a small committee in each region. The term of office would end when the new service begins.

We believe that these proposals should in some measure mitigate the uncertainties of the present time, while the country would surely gain.—We are, etc.,

Bread Rationing

SIR,—Apparently, from the published scale allowances of Bread Units, the school boy or girl and undergraduate on attaining the age of eighteen years is classed as a normal adult, and his or her B.U. allowance per week drops from 12 to 9; while, should he be lucky enough to become a manual worker, he gains 3 B.U.s per week. Increase of growth is possible up to the age of twenty-five years, and in addition to this there is the added strain of scholarship work and the responsibilities of leadership entailed by monitorial and other activities in the one class, which correspond closely to the extra output which is apparently and rightly expected from the manual worker.

Statistics kept at Christ's Hospital since 1913, of which I only quote two periods of six years each (namely, 1933 to 1939, and 1939 to 1945), give a fair comparison between a non-ration and a ration period.

The improved tar preparation

E.S.T.P.

BRAND

(MARTINDALE)

Ether Soluble Tar Paste

Purified, decolorised, non-staining,
aromatic; maximum Tar effect

FORMULA

Ether Soluble Tar Distillate ...	1.5%
Zinc Oxide ...	14.0%
Starch ...	24.5%

In a special emollient base

A smooth paste easily applied. The tar component retains the essential phenolic compounds unimpaired, ensuring powerful antiseptic action. All indications for Tar Treatment are indications for "E.S.T.P." (Martindale), more especially infantile eczema; eczematosa generally; impetigo complicating eczematosa; prurigo; pruritus; psoriasis; pityriasis circinata; lichen planus. In 2 oz. and 16 oz. pots. Sample and literature on request.

Vitamins in Obstetrics

For more than 18 years Vitamins Ltd., have been working on nutritional subjects. During that time, dramatic advances have been made in the recognition of deficiency conditions and diseases, and in the appropriate uses of vitamin therapy.

In pregnancy, when dietary requirements are raised, it is important to take prophylactic measures against the development of latent deficiencies.

Condition	Indications	Therapeutic Agents
STERILITY Sub-fertility Habitual or threatened miscarriage	These conditions when not traceable to structural or endocrine abnormalities may be associated with a deficiency of vitamin E.	FERTILOL (Wheat germ oil stabilised and standardised) 1 to 3, 3 mg. caps. daily. BEMAX contains vitamin E (8 mg. per oz.) and other factors which may be important.
PREGNANCY TOXAEMIAS	May arise when the extra demands of pregnancy are not met in the diet.	PREGNAVITE TABLETS . A comprehensive dietary supplement designed to meet the pregnancy requirements of the important vitamins and minerals.
HYPEREMESIS GRAVIDARUM	May be one sign of the above.	VITAMIN B₆ (Pyridoxin), 10 to 20 mg. thrice daily. VITAMIN B₁ (Aneurin hydrochloride), 10 mg. or more daily.
OEDEMA	As in beri-beri and congestive failure may in some cases be associated with vitamin B ₁ deficiency.	VITAMIN B₁ (Aneurin hydrochloride) 3 to 10 mg. daily.
HAEMORRHAGE In the newborn	To raise prothrombin levels in the first days of the infant's life.	VITAMIN K . 10 mg. tablets, one daily to the mother or the contents of 1 Ampoule to the infant.

NORTHWOOD

MIDDLESEX

For sustained control of gastric hyperacidity

NOVASORB

(Hydrated Magnesium Trisilicate)

Novasorb provides for sustained control over gastric hyperacidity without producing an alkaline condition in the stomach. It thus presents a desirable improvement over the older antacids, where control is limited to the immediate reaction and where continued administration of excess alkali may induce alkalosis.

High adsorptive properties

Will not give rise to alkalosis

With suitable doses, does not destroy peptic activity

A safe antacid for general use

The Novasorb brand of hydrated magnesium trisilicate was developed and introduced by Evans Fine Chemical Works and is based on original observations and clinical trials (Brit. med. J. 1936, I, 143, 205 and 254).

Issued in Powder and Tablet form.

WATERLOO ROAD, LONDON, N.W.2

From 1933 to 1939 the figures show that of an average of 10.5 boys: 17 were over 18 years; 77.8 were under 11 years; 15.7 were between 11 and 18 years. Their allowance under the suggested scale would be 9,403.8 B.U.s per week, but during this period they ate the equivalent of 10,009.6 B.U.s per week. Each boy's requirements on an average thus exceeded the suggested allowance by 0.747 B.U.s per week.

From 1939 to 1945 the figures show that of an average of 10.38 boys: 13.9 were over 18 years; 75.7 were under 11 years; 14.2 were between 11 and 18 years. Their allowance under the suggested scale would be 9,457 B.U.s per week, but during this period they ate the equivalent of 11,526 B.U.s per week. Each boy's requirements on an average thus exceeded the suggested allowance by 2.47 B.U.s per week.

Appetite and requirement vary with the individual, and it is impossible to assess within narrow limits, but these figures prove that the average requirement per boy is greater than the suggested allowance. It is of importance to note that just as in 1914 to 1918 the consumption of bread increased proportionally with the reduction of meat and fats, so from 1939 to 1945 a similar increase has occurred. It is fair to expect that if the suggested restriction is enforced, the rate of growth, which in my opinion is a reliable index of the general health of the adolescent, must show a regression.

It has been suggested that the vacuum can be filled by potatoes, which now seem to be the only substitute available without points. The objections to this, which should be obvious, are these: (1) The amount of potatoes which the English adolescent will consume is limited. (2) Recent experience has shown that the supply of potatoes can be very variable. (3) In institutional catering shortage of labour and equipment put a definite limit to the quantity of potatoes which can be handled.

Surely it follows that in any plan which has the interest of the future generation at heart, it would be wise not only to increase the allowance for all adolescents, but also to make one class of all students from 8 to 25 years of age.—I am, etc.,

G. E. FRIEND,

Medical Officer, Christ's Hospital.

Horsham.

Inadequate Feeding in Hospitals

SIR,—The report of Major J. A. F. Stevenson, Capt. Joan Whittaker, and Lieut.-Col. R. Kark (July 13, p. 45) of their inquiry into the adequacy of feeding in Canadian military hospitals hits several nails right on the head, and provides me with a most appropriate excuse for drawing attention to another aspect of the same question. I am a chemist with special interests in the field of nutrition, and a close relative of mine was recently appointed as head cook at an isolation hospital under a local authority in whose public health department I have other contacts. On the evidence which has thus become available to me, I am appalled at the inadequacy of the diets provided. Moreover, while this is admittedly but a single instance of hospital practice, it is most unlikely to be an isolated one, for the two main reasons for the trouble probably hold good in many—perhaps the large majority—of the hundreds of similar institutions scattered about the country.

In the first place, the menus are the sole responsibility of the matron (there is no sister housekeeper), who appears to know nothing, and certainly cares less, about the importance of an adequate and appropriate diet for patients suffering from infectious fevers. The medical officer takes no interest in this side of the hospital administration. In the second place, the cost of "food-plus-medicines" per patient-day is a statistic which is calculated every week; both the matron and the M.O.H. eagerly watch this figure, and obviously take it as one of their primary duties to keep this cost at the lowest possible level. The M.O.H. has often, in his reports to the public health committee, told them how cheaply he runs their hospital for them, quoting the statistic in question as proof. It occurs to no one that the patients' recoveries might well be hastened, the average stay in hospital per patient reduced materially, and a saving effected on the total cost of running the hospital if the diet were improved.

I am certain, on the evidence presented to me, that the recovery of many patients must have been seriously delayed by the gross inadequacy of their diets, both in quantity and quality. Space does not permit me to detail the many facts on which

I base this statement. It will be sufficient if I quote but one. During one continuous period of nearly four months, no kind of green vegetables or fruit was served; and this in spite of the fact that the vitamin C requirement is known to be considerably enhanced in febrile conditions. To my mind this dietary crime is made the more heinous by the fact that practically all the patients in such a hospital are naturally children, who, however unattractive or insufficient they may find their meals, do not realize that conditions could be very different. Even the meals that are served to the nursing staff are dietetically shocking and far too low in calories; all the nurses are in the habit, from sheer necessity, of buying supplementary food outside.

It is high time that the medical superintendents of hospitals appreciated the prime function of diet as a major therapeutic adjunct; that governing boards and controlling committees were taught to recognize that money spent on food is every bit as essential, and yields at least as large a dividend in the form of health, as that which is spent on drugs; and that an interest in the dietetic well-being of the patients should be carried right into the wards, for it is only those who come into immediate daily contact with the patients who are in a position to see whether what the patient is given to eat is not only qualitatively and quantitatively adequate, but is presented in an attractive and appetizing form. Some of these points have already been made in the recent memoranda of King Edward's Hospital Fund, and I do not suggest that there is anything original about the sentiments expressed in this letter. I do believe, however, that the matter is one about which something would have been done long ago if only the fierce light of publicity could have been made to beat upon it soon enough and for long enough, and I should like to think that the paper by Major Stevenson and his collaborators will result in similar studies being made in British hospitals, and the directing of attention to a very bad business.

Since publication of my name would probably result in local identification of the hospital to which I refer, I will ask you not to publish my name and address, but I enclose my professional card.—I am, etc.,

"DIETIST."

Tuberculosis under the Bill

SIR,—In your annotation of July 6 (p. 20) reference is made to the anxiety felt lest the arrangements under the new Health Service Bill for dealing with the tuberculosis problem should prove a retrograde step. The intentions of the Minister are not yet stated in detail, but the proposed division of responsibility for the various aspects of the new scheme carries a serious risk of disruption unless proper co-ordination can be achieved. This will not be easy, since the established principle of control of all aspects of each case by the tuberculosis physician may conflict with administrative arrangements for the provision of certain necessary facilities. Thus we have the prospect of the clinical, environmental, insurance, and rehabilitation aspects of each case being dealt with by separate authorities. Into this complicated pattern a complete tuberculosis service must somehow be fitted without interfering with the physician's control of his patients, or his freedom to guide them through the many difficulties with which they are faced. The danger lies in each of the authorities concerned attempting to assess the needs of a case for themselves, possibly with separate medical advisors at each stage, instead of acting directly on the basis of an assessment made by the tuberculosis physician himself, whose decision should be final. It is essential that this latter method be adopted, and practical arrangements must be made accordingly.

The first requirement is that all cases of the disease, of any type, should be referred to the new hospital chest clinics, so that the environmental aspects of each case may be dealt with by the physician to that department. He will, in any event, be dealing with the pulmonary cases which form by far the greater part of the problem, and while leaving clinical control of non-pulmonary disease in the hands of his colleagues, he can most easily supervise social and preventive measures as a whole. For this purpose he should have direct control of the nursing and health visiting staff of his clinic. The duties of such staff are becoming increasingly those of out-patient department nurses, associated with social work in the home, in about equal proportions. The proposal in the Bill is that all health visiting

staff shall be employed by the local authority. There does not, in fact, appear to be much justification for this; it would be better if they were employed by the hospital authority itself. Whatever the final decision may be, they should certainly work full-time at the chest clinics, under the control of the clinic physician. The local medical officer of health, responsible for environmental conditions generally, would receive reports from the clinic, as he does now from the dispensaries, whether it is under the same authority or not.

As regards financial aid, it appears that the tuberculous patient will be paid from a common insurance fund. The assessment of need, however, should be carried out at the chest clinic, where it is hoped there will be adequate welfare staff to deal sympathetically with such matters under the direction of the physician. Rehabilitation and placing in industry is to be the responsibility of the Ministry of Labour; already memoranda and forms are circulating. Routine form-filling will not do in this case. The tuberculosis physician should have detailed knowledge of posts available in local industry under the quota, and should be able to settle questions of placing directly with the D.R.O. Sheltered employment is to be provided for the less fit. Units of this kind must be regarded as having more a clinical than an industrial function. Here particularly the physician should have control and should exercise a general supervision in all medical aspects of the scheme.

Altogether recent developments and proposals for the future offer much that the tuberculosis service has sought for years past: a much closer contact with general medicine, financial assistance for the patients, and schemes for protected conditions of employment. It is not the principle that is questioned, but the possibility of a ponderous administrative machinery breaking down what should be a unified scheme into uncoordinated sections. This can only be avoided if officials of all kinds regard themselves as a single group concerned primarily with the welfare of the patient, no matter what authority employs them. Above all, the tuberculosis physician must be in control at all points where medical direction is essential. If the Minister will ensure this when the time comes for deciding practical details, all may yet be well,—I am, etc.,

Theydon Bois, Essex.

HUGH RAMSAY.

Duodenal Ulceration

SIR,—Mr. Harry Freeman is to be congratulated on his interesting paper (June 29, p. 980). His description of the subject presenting symptoms of duodenal ulceration as "an extremely sensitive and hyper-irritable type in a constant state of nervous tension . . . above all he is stomach conscious" is the most complete and accurate picture in a few words that I have yet seen.

How many of even our most eminent consultants remember this in dealing with cases of this type? Mr. Freeman's ligature operation, gastrectomies, and gastro-enterostomies will still be required, as well as "medical treatment"; but his statement regarding gastrectomy, "the creation of a very grossly distorted anatomy and a grossly deranged physiological function of the stomach does not seem rational in the quest for a cure of a condition the aetiology of which is still unknown," is surely a lamentable fact.

Is it too much to hope, that—remembering Mr. Freeman's description of the type—the key to the problem lies in the hands of the psychiatrist?—I am, etc.,

Newark.

J. J. KENNEDY.

The Hypochondriac's Treatment

SIR,—I venture to comment on the remarks of Drs. Summer-skill, Cox, Lindsey Batten, and Crichton-Miller in regard to cases of hypochondriasis treated under private medicine or under a State system. Surely the main point is that hypochondriacal patients are ill, and should have whatever treatment or sympathy is available, whether it is paid for and sought by rich private patients or by poor patients who are entitled to national State medicine. Rich patients and poor patients of a hypochondriacal type are not to be cold-shouldered because they are very rich or very poor. Surely the time has come when the actual needs of the patients come before the prejudices of caste or the narrowness of social theories.—I am, etc.,

London, N.W.11.

L. S. WOOLF.

SIR,—In adverting upon our new charter of liberty I seem, unintentionally, to have opened a discussion on the hypochondriac's treatment, and I must now endeavour to set myself right with Dr. H. Crichton-Miller (July 13, p. 62). I fear we have all used the word "hypochondriac" too loosely. It covers two kinds of patient, and though the line of demarcation is a little hazy most people with "functional symptoms" can, I think, after a few interviews, be placed where they belong.

Those in the first group are, very nearly, "conscious delinquents." They use their symptoms quite flagrantly to evade duties and secure sympathy. They exploit friends and relations. They try at once to use and to irritate their doctors as a spoilt child will use and irritate its mother. They have no intention of getting well. These people are usually, though by no means always, well off. I do not believe they are very numerous, and their chief importance lies in the ammunition they provide for Socialist propaganda. *Tout comprendre c'est tout pardonner*, but we are only human, and as they discard their doctors without compunction it seems to me at least excusable, on occasion, to discard them. To tell one of them plainly to seek another doctor is a grand tonic for self-respect, and I know nothing which gives a livelier sense of the freedom we still enjoy. It is well worth its price in guineas. I suspect, too, that it is good psychotherapy.

The other kind is the anxious and fearful person of every class and income level. These people do, indeed, bulk large in every practice. There are days on which I seem to have done nothing else than to attempt to dissect the clinical pictures they present, evaluate their symptoms for them, and try to allay their fears. I confess I believe they are very often incurable, whether by psychologists or anyone else, but I am certain that with wiser upbringing at home and more imaginative and courageous medical advice in childhood and youth, many of them need never reach the sad state in which we find them. Typically they are people who prefer security to adventure, integrity of body to integrity of soul, dependence to independence. They would sooner save their lives than live them, and in their eyes the unforgivable medical sin is to fail to discover or disclose a danger, to accept or, worse still, advise the, taking of a risk. Since their philosophy is the familiar guiding principle of British bureaucracy, and since bureaucracy is grasping both medicine and education, I fear their numbers will greatly increase. Often enough their one friend is their doctor, but he must have time to listen, time to advise, time to do it again and again, and, unless he be a saint, some direct incentive, such as undivided responsibility and perhaps even a fee to encourage him to lift and carry this heaviest of professional burdens. To disclaim responsibility for them is in the highest degree unjust, but I shall be astonished if the service does anything more for them than to send them round in circles from one irritated specialist to another, until they sicken of it and seek whatever help may remain to them outside.—I am, etc.,

Hampstead, N.W.3.

LINDSEY W. BATTEN.

Protection against Sexual Offences

SIR,—When sentencing a man to two years' imprisonment for assaulting a six-year-old girl at Birmingham, Mr. Justice Croom-Johnson said that this was the maximum sentence he was allowed to pass, and added, "Our law—and at the risk of being misunderstood I intend to say it—does not pay sufficient attention to the protection of women and girls with regard to many sexual offences." It is to be noted that the man upon whom he passed this sentence had been released three weeks previously after serving eighteen months in prison for a similar offence.

It is without any sense of criticism that I heartily concur with the learned judge and agree that the law does not offer any protection against this type of offence. Men suffering from sexual neuroses are sentenced to imprisonment, where they have no treatment whatsoever, and after a period of years (during which they suffer sexual deprivation) they are released with increased urges and commit the same type of offence again. It is obvious that incarceration does not affect the man's condition—except adversely—one iota. The only solution to this problem would be to give the prisoner a life sentence or else to regard the behaviour as an illness (which every psychiatrist knows it is) and treat it.

it is customary for judges to say that if treatment is necessary it will be given in prison. I have taken the trouble to wire from patients I have had who have served sentences such offences and the reply has always been "None whatever." A short while ago there was a correspondence in the *Journal* on the neuroses due to confinement in prisoners of war, and the general opinion appeared to be that being immured did produce abnormal mental states. How much sense is there in putting the already abnormal in a place where—unless they are treated—they will become more so?—I am, etc.,

London, W.1.

CLIFFORD ALLEN.

Treatment of Bacterial Endocarditis

SIR,—The medical world is now much intrigued by the result of treatment of bacterial endocarditis by penicillin and by the appointing results of the sulpha drugs. We have been over-one to label diseases by certain names and to refuse to recognize any variation which did not comply with certain definitions. One hears men discussing the exact types of aemias, nephritis, and many other conditions in which there is no clearly defined line of demarcation, instead of recognizing the pathogenesis in process. It is all very well talking about bacterial endocarditis as if it is a *fait accompli* and starting off on there to treat it, but it is far more important to try and analyze how it comes about, for once that is understood our lines of treatment may be much modified.

Bacterial invasion of the blood stream in many people is almost daily occurrence, but it does not lead to their deaths, because the defence mechanisms are able to destroy the organisms, either in the blood stream or in such tissues as they may lodge in, as is seen in abscesses, nephritis, arthritis, etc. For organisms to enter the blood stream they must have a point of entry, and they must also have the power to multiply in such places where they are uninfluenced by any means the body has to destroy them. In many of these cases the breeding ground is in such a protected focus that the defence mechanisms are unable to overcome the invaders. This we see in infection within the cavity of the uterus, tonsillar crypts, between the gums and the teeth, within the cavity of a dead tooth or nasal sinus, so we must look upon these foci as being guarded by a trap-door or valve through which the micro-organisms can slip but nothing can get in to irritate them.

In the majority of cases the defence mechanisms of the blood and tissues are able to destroy invaders before they have done too much damage; but once this power is lost the organisms overwhelm the host, as is seen in fatal cases of septicaemia, of which bacterial endocarditis represents a certain proportion. Of the large number of cases of septicaemia from puerperal infection only a small proportion develop bacterial endocarditis. In such conditions we must suppose the myocardium and valves to have become sensitized, or that the strain of organism had a specific elective affinity for those tissues. Some of the commonest causes of severe and fatal bacteraemia result from dead teeth, extractions for pyorrhoea, removal of septic tonsils, as well as uterine infections. With regard to root abscesses, which are frequently devoid of pain, and so give no warning of their presence, they have no outlet for the infection except into the blood stream.

The removal of teeth for severe pyorrhoea is always a serious undertaking unless a cleaning-up process is carried out beforehand to reduce the infection, and then only a few teeth must be extracted at a time and much time be allowed to elapse before others are drawn, to escape the negative phase. It may even be desirable to give a course of vaccine treatment to boost up the defence mechanism, especially if many teeth have to be extracted at once. This same procedure may be advisable in the removal of tonsils, where the hunter-guillotine is used, as there is a risk of forcing organisms into the tissues; but where a clean dissection is employed this danger is much reduced.

On the whole the defence mechanisms of the blood are able to deal with a few stray organisms entering the blood stream, but if they should come in in overwhelming numbers, this mechanism may be taxed beyond its power, so that organisms multiply within the blood stream with fatal results. In the presence of any septic focus organisms are liable to enter the blood stream daily for a prolonged period with little to show for it, but with the extraction of teeth and the removal of tonsils or some flare-up in the focus they may then enter in overwhelming numbers.

With this view in mind the approach to the treatment of bacterial endocarditis should be totally different from saying, "Here is a case of bacterial endocarditis, let us give it penicillin." The first objective should be to try to find where the organisms are coming from and close the door by the removal of the focus, as those that are already in the blood stream will

be much more easily dealt with if a fresh supply is not coming in daily. There are some who doubt the ability of organisms to breed in the blood stream and maintain that bacteraemia is only kept up by continuous entry. So in spite of the ill condition of the patient it is sound policy to remove any source of entry. Nasal sinuses, especially when blocked, are very apt to be overlooked. I feel sure that such lines of treatment would lead to a greatly improved percentage of cures.—I am, etc.,

Ballarat, Victoria.

SYDNEY PERN.

Allergic Response to Penicillin

SIR,—The following account of what appears to be an allergic phenomenon due to penicillin may interest your readers.

About fourteen months ago I was making a bronchoscopic examination on a "clean" case and the patient happened to cough into my right eye. I omitted the usual prophylactic precautions owing to pressure of work, and next day I had a mild conjunctivitis. This was swabbed for purposes of culture and examined by an ophthalmic surgeon, who found no injury to the cornea and advised penicillin instillation if the culture showed penicillin-sensitive organisms present. These were found, and penicillin in normal saline at a strength of 1,000 units per ml. was instilled, a drop or two at a time, every three hours.

My eye became steadily worse, both lids becoming red and swollen so that I could only just open them actively, and the surface of the skin of the lids and the free margin began to desquamate. Slight irritation of the skin surface of the inner canthus of the other eye also occurred. After three days, on the advice of the specialist, the penicillin was stopped and "albicid" (sulphacetamide) instilled instead—I forget the strength. The condition of the eye and lids immediately improved and had returned to normal in forty-eight hours, except that some desquamation continued.

About two months later, a recurrence of the irritation, especially of the lid margins, took place. Penicillin was tried once more, resulting in an immediate flare-up of the lids to their former condition. All this subsided as soon as albucid was substituted for the penicillin. About three months later, there was a slight recurrence of the irritation, which cleared up with albucid. I had no further trouble until a fortnight ago.

I had been in hospital for a week, after an abdominal operation. I have a very old left mastoid sinus which occasionally discharges, and it was decided to culture it with a view to local treatment while I was an in-patient. Very few organisms were present, but as they were mixed and all seemed penicillin-sensitive, insufflation three times daily of penicillin and sulphathiazole powder was suggested, to which I agreed.

Twenty-four hours after the first dose into my left mastoid cavity, my right eyelids became red, swollen, and sore—the pain being felt as a constant burning sensation on the skin surface—not unlike that following over-exposure of the lids to sunshine. The lid margins were irritating, and after twenty-four hours slight desquamation started. I am told the conjunctiva was infected, but at no time did I experience the symptoms of conjunctivitis.

The insufflations continued for three days and were then stopped. Throughout this time the lids remained "inflamed" so that visitors kept remarking I was getting a sty. The irritation, burning, and scaling also involved the right eyebrow, a small area of the right forehead, a small area of the right cheek immediately below the eye, and the inner canthus of the left eye. At the same time a similar condition occurred in the meatus of the left ear and behind the lobe of the ear.

There was never any local site of tenderness nor the massive lid oedema that generally occurs with a sty, and as I was convinced it was an allergic phenomenon, no local treatment to the eye was carried out. The insufflations were stopped five days ago and the condition of the eyelids immediately improved. Two days later, the "stain" of penicillin was still present on cleansing the left ear, but was greatly diminished. The meatus was far less irritating and the burning and discoloration of the eyelids had subsided completely, although there was slight irritation from the finely desquamating skin of the lids, chiefly in the region of the inner canthus.

For the past two days I have been completely free from irritation or any other symptom both in and around my right eye and in my left ear.

Another point that may have some bearing on the two earlier recurrences of this unusual condition was that I was at that time penicillin officer in the hospital in which I worked and handled penicillin daily in one form or another, and it is quite possible that a trace of penicillin at that time was the cause of the flare-up. If penicillin can cause this type of reaction around an eye, it is equally likely to cause it elsewhere in the body where penicillin has been applied locally, and this should be borne in mind.—I am, etc.,

London, E.1.

W. R. WELFELY.

Varicella Herpetiformis

SIR,—I was interested in the memorandum on varicella herpetiformis by Dr. P. H. Peterson and Dr. S. A. B. Black (May 18, p. 762) because of a recent case here. This sparsely populated district in N.W. Canada is isolated by over 60 miles (96 km.) of forest from the nearest other settlement. In April it is completely cut off by the spring thaw and the break-up of ice in the rivers. There is not even a mail service during this month. It is, therefore, almost as much an island community as the Shetland Isles. With the exception of the cases described there have been no cases of chickenpox or herpes zoster in this community for the past 15 months.

Case 1.—April 7, 1946, I was called to see a very mild case of chickenpox in a 2-year-old girl. The family had moved into this district from a village 180 miles (288 km.) away, seven days previously. The child had been playing all afternoon with a family of three cousins, none of whom had had chickenpox, on the day the rash was first noticed, April 6. There was no further contact between the families till this case had cleared up.

Case 2.—April 15, the eldest of the cousins, aged 6, developed a typical well-marked herpes zoster over the left lower ribs. There was no pain or malaise.

Cases 3 and 4.—The two younger cousins, aged 8 months and 2 years, developed moderately severe chickenpox.

Since all other sources of infection can be excluded in this isolated community, it seems much more likely that Cases 3 and 4 contracted chickenpox from their brother's herpes than that they contracted it from Case 1, and developed it simultaneously after an incubation period of 24 days. It will be interesting to see if the boy who had herpes will prove immune to chickenpox when we next have an epidemic. It is remarkable that he did not catch it from the other two cases in the house if his herpes had no connexion with chickenpox.—I am, etc.,

Keg River, Alberta.

MARY PERCY JACKSON.

Migrainous Headaches

SIR,—Dr. Wilfred Harris in his letter (July 6, p. 24) seems to miss the point of my criticism of his paper. If his operation is successful he will get not analgesia of the cornea, but complete loss of sensation. This is such a serious state of affairs that it should be stressed. The palliatives he suggests are excellent in themselves, but how can a man or woman continue to use them if he or she is to live a normal life? This anaesthesia of the cornea will last for ever, or else the neuralgia will return.—I am, etc.,

Plymouth.

CECIL B. F. TIVY.

"Drug Eruption" following Sodium Pentothal

SIR,—With reference to the case reported by Dr. G. A. Grant Peterkin (July 13, p. 52) of skin eruption following sodium enthal, two cases of a somewhat similar nature occurred during my service as anaesthetic specialist at a British military hospital in India. Both were healthy British soldiers undergoing minor orthopaedic procedures on the same day. One received 0.75 g., the other 0.5 g., pentothal. On the following day, each patient had a temperature between 100 and 101° F. (37.8 and 38.3° C.), an urticarial rash, sore throat, and coryza. These symptoms disappeared within forty-eight hours. In investigating these cases, I had samples of sterile, distilled water examined from the same batch used. These were manufactured by an Indian firm of druggists. The pathologist reported the samples to be heavily contaminated with *Bacillus subtilis*.—I am, etc.,

London, W.4.

DONALD BLATCHLEY.

Black Tongue

SIR,—The letter on this subject (July 13, p. 63) prompts me to record an experience of my own. It happened twenty years ago when I was called early one morning to see a woman patient who was in a great state of alarm on finding her tongue to be intensely black. There was nothing else the matter and there appeared to be no cause. There was only one possible origin and that was the eating of boiled eggs that morning. I was able to allay my patient's fears by suggesting that the

blackness was due to the sulphur in the eggs and that it would pass off in the course of a short time. That is what did happen. I also suggested that she should repeat the experiment after the lapse of a few days. This she did, and the black tongue reappeared. She had, of course, eaten boiled eggs many times before but had possibly never noticed this particular effect on any previous occasion.

My book of notes on *Curious Happenings* has recently been stolen, and I am unable to make any addition to this simple statement of fact, except that I have noticed the relationship between boiled egg and black tongue on several occasions in other patients, but the blackness has never been of the same intensity as in the first case.—I am, etc.,

Chelsea, S.W.3.

A. R. EATES.

Health Service Bill

SIR,—Within a month or two we may expect to see the National Health Service Bill reach the statute book, unaltered in all essentials. There has been widespread talk of a "refusal of service" in such a case. This obviously does not mean that we shall refuse to attend the sick at all, but simply that we shall refuse to attend them under the provisions of the Act but will continue to do so as private or Public Medical Service patients. What will be the economic effect on the Government, on the public, and on ourselves? The Government will gain enormously. It will, directly and indirectly, draw vast sums from the public without the obligation to pay the doctors a single penny. The public will be very little affected. It will receive the same medical treatment as heretofore. Its economic position will be so much affected by the compulsory Government levies that it will receive this treatment either gratuitously, or at a mere fraction of its former fees. The doctors will be the only losers. They will do the same work as before at greatly reduced rates. In addition, as there will be neither a mileage nor a drug fund, their expenses will be appreciably increased. So far as the Government is concerned, the situation can certainly be prolonged indefinitely; as regards the public, probably so; as regards the doctors, there is a definite time limit, which I put at not more than six weeks.

My argument is this. Except so far as purely cash practices are concerned, we live in any given quarter on the takings of the preceding quarter. For the first three months of the "strike" we shall therefore be able to subsist comfortably on previous earnings, but after that we shall be in dire straits, having to carry on largely on bank overdrafts. It must also be remembered that after the "strike" is settled, one way or another there will be nothing forthcoming from the Government until the end of that quarter, and that the longer our resistance is prolonged the worse our plight will be. For that reason I put the duration at not more than six weeks. The levy of £25 head now being called for by the B.M.A. does not affect the situation one way or another. It represents as nearly as can be one week's earnings of the average doctor (£1,300 p.a.). It means that we pay in one week's earnings now with the prospect of getting it back in instalments later on. We should be precisely as well off if we paid the same amount into our bank against the coming "rainy day." Such additions as the B.M.A. may be able to make to it are negligible considering the number of doctors concerned.

Is it probable that six weeks' refusal of certificates, for that is what resistance practically amounts to, will bring the Government to its knees? I regret to say that I do not think so. In the first place, the Government, by eliminating the friendly societies, has left itself entirely free to determine what form of "sick certificates" it will require. In an emergency, and for a short time, it might consider the production of a recent prescription or of a freshly issued bottle of medicine (neither of which we can refuse) to be enough. Further, by refusing to accept Government pay, we shall have obligingly provided it with a fund large enough for it to face a certain amount of fraud with equanimity.

My regretful conclusion therefore is that we shall be well advised to think twice or three times before embarking on a plan of action which will enrich the Government, impoverish ourselves, and have no decisive effect. What other possibilities there are, I will not attempt to discuss at present.—I am, etc.,

Andover.

J. A. BALCK-FOOTE.

SIR,—The decided opinions of Dr. J. V. Dockray (June 29, 1939), based on political conservatism and the desire to uphold the dignity and nobleness of the profession, provoke a reply. He states: "organized refusal to work the Bill is a rife." I doubt it. The essence of a strike is the withholding of one's labour. It is one of life's thrills that has been enjoyed by many who are thrusting the new health service upon us, and an adventure on which many doctors would, for various reasons, hesitate to embark, however modified the "strike" might be. Refusal to serve under contract with the new employing authority cannot be termed a strike if the Act leaves all of us free to engage in private practice.

It is generally agreed that our medical services will never be withheld. If we revert to private practice, giving the assurance that every sick person will be attended, thereby rendering to the community the essential service for which we were trained, up to that point there is no strike. But certification to enable people to draw statutory sick benefit is also an essential service under modern conditions, and if even as private practitioners we withheld that service, that would be a partial strike, and perhaps the extreme limit to which general practitioners would go. It is the form most likely to meet with success, and is true to the pattern of the workers' strike in that it would primarily embarrass the employer and secondarily cause inconvenience to the community. If carefully planned it need only be of short duration, thereby minimizing the hardship to the people. Dr. Dockray states that "the great majority of the people are in favour of the Bill." My feeling is that the masses are innocent and passive spectators in the present medico-political struggle, and will not express themselves sufficiently unless under the stimulus of some impending inconvenience. If Government and people failed to respond after several months' notice of our intentions, our subsequent action might be considered morally justified. The distribution of public funds would be no responsibility of ours.

If such action were timed to commence on "the appointed day" the chances of success would be good, even in industrial areas. Existing economic conditions are likely to prevail for some time, and recent years have shown that the masses are willing to pay for medical attendance when they are able. Arising from the scarcity of commodities and the abeyance of the evils of the instalment system, the display of bank-notes in surgeries is quite embarrassing. With a country full of bank-notes and full of disease it is hard to imagine a set of circumstances better calculated to ensure success in the sale of medical attendance. But success would be uncertain unless under an organization where central instructions demand peripheral obedience. Mere promises of action by the rank and file are apt to collapse as a result of mutual suspicion and distrust.

The impact of the National Health Service Bill has brought the subject of trade unionism into practical medical politics, as it is important to ascertain the degree to which collective action may be expected to function in an emergency. It may be anticipated that the early years of the operation of the new Act will be very toilsome ones for many general practitioners, pending the training of a sufficient number of recruits. Cases of hardship are likely to arise, and something like trade union methods may be necessary to ensure that a practitioner with a just grievance can rely on the support of his combined fellow-practitioners.

In the matter of collective bargaining we do not appear to have had any distinctive successes in the past. The Spens Committee has shown (perhaps not yet to the satisfaction of the Minister of Health) that for many years general practitioners were underpaid, yet in spite of approaches to successive Ministers of varying political convictions we observed during the inter-war period the movement of the capitation fee from the ceiling down. And there exists in the mind of the layman a delusion that the B.M.A. is a very powerful trade union. Observe his look of mingled suspicion and incredulity when he is informed that the B.M.A. is not a trade union at all. He does not know, and many members seem to be unaware, that the Memorandum of Association of the B.M.A., confirmed by the Chancery Division of the High Court of Justice, contains a prohibition as follows: "Provided that the Association shall not support with its funds any object or endeavour to impose on or procure to be observed by its members or others any

regulation restriction or condition which if an object of the Association would make it a trade union."

There already exists what may be termed in these columns "a certain union," with a membership that is far from negligible. Is it too much to hope, in these critical times, that a *rapprochement* might be effected in an effort to promote concerted action? The profession, having lost a certain amount of freedom, is forced to consider how far, in the interests of a shoulder-to-shoulder system of defence, it is prepared to submit to a self-imposed dictatorship within its own organization. General practitioners already have the framework in the Insurance Acts Committee and the Panel Committees. The personnel of the existing I.A.C. could, with their own assent and the approval of practitioners, assume the necessary functions as a collateral activity. Members would be asked to bind themselves to act in accordance with instructions received. The financing of such an activity would presumably (at the beginning) be a legitimate charge on the National Insurance Defence Trust. A questionnaire might be sent round. Answers would vary according to temperament, politics, religion, social consciousness, etc., but the present seems opportune to sound the profession on the subject.—I am, etc.,

Glasgow.

J. N. JAMIESON.

SIR,—I should like to congratulate Dr. W. Edwards (July 6, p. 27) on his splendid letter. I agree with every word of what he says; in fact, I made a similar plea as strongly as I could at the last Special Representative Meeting.

The issue before us is a simple one—it is a moral one—the choice between good and evil. The methods suggested in the Bill will lead inevitably to evil for the patients and ourselves. We must stick to our guns to maintain freedom in this country, and if we do we shall win. There are two ways of doing this. *First*, that every medical man at once send in his guarantee of at least £25 to the Guarantee Fund so that the profession can help those who may be temporarily in financial difficulties as a result of their courage. *Secondly*, at the appropriate time every man and woman in medicine who realizes the urgency of the great issue at stake must guarantee not to join the new service. I have no doubt that the majority of doctors in their heart of hearts disapprove of the totalitarian methods of the Bill.

There is no need to strike. We can continue to treat and serve our patients. All we have to do is to refuse to join the new service, and from the Guarantee Fund to back each other up and maintain our unity—if we do not, every one of us and every one of our patients will live to regret our failure to stick to our moral principles.—I am, etc.,

Reading.

S. F. LOGAN DAHNE.

Pay-beds in a Municipal Hospital

SIR,—It may interest your correspondents to know of an experiment in the organization of pay-beds that has been successful here for fifteen years. Each general ward in this hospital contains 30 beds, and has three side-wards which are utilized for the nursing of cases requiring isolation, privacy, or special care. The first full-time medical superintendent introduced their utilization, when not needed by ordinary hospital patients, for private patients who paid a weekly charge to include all investigations and treatment, including operation. This was so successful that when I took over nine years ago we introduced a further block of 20 single rooms on the same principle. The rooms are available to anyone, on their doctor's recommendation, who cares to pay for them. They are also used for ordinary ward patients when the side-wards are otherwise occupied (at the moment a large number are being used to house an overflow from the maternity department). Patients admitted to these rooms are treated medically as any other hospital patient, they are under those members of the staff who see them as out-patients, or to whom they are referred by the medical superintendent. The terms of appointment of consultants to this hospital contain the proviso that they shall see and treat any patient in the private ward at the request of the medical superintendent, this without special fee, but that where the consultant's advice is requested by the patient, or the patient's own doctor, then the consultant can charge any fee he desires. This applies also in the case of any patient sent into the private ward at the request of the consultant.

This system has worked smoothly and to everyone's satisfaction. The patients can obtain the privacy they desire if they care to pay for it, the facilities are available for other patients where, in the opinion of the medical officers, such isolation is indicated on medical or other grounds, and they provide a number of beds for fee-paying private patients. There is no control as to fees charged—they have varied from three guineas to a hundred. No salaried member of the staff may charge fees.

Although it bears no relationship to the above, I should like to comment upon the remarks of Dr. G. C. Pether (July 13, p. 65) concerning administration in municipal hospitals. I have no hesitation in summarily dismissing from hospital any patient who is abusive, unnecessarily rude, or obstreperous. Where these characteristics are due to their illness we transfer them to a side-ward, or when mentally deranged to a mental observation ward in another hospital. I have a "black list" of patients so discharged whom I refuse to admit again to hospital. In each case I note the reasons for such abrupt dismissal on the case card, giving names, times, and instances. So far no patient so dismissed has had the temerity to refer the matter to the hospital committee.—I am, etc.,

H. I. DETTCH,
Medical Superintendent.

Halifax General Hospital.

Socialism and the Pay-bed

SIR,—While sympathizing with the "refined, sensitive, and intelligent" mentioned in Dr. G. C. Pether's letter (July 13, p. 65), who will doubtless suffer agony in a public ward, whether the next patient is "foul and obscene" or not, I cannot desist from pointing out that our Hippocratic oath should protect not only those who can pay for a private bed but also those who cannot. In my experience, the refined, sensitive, and intelligent occur just as frequently in the one class as the other, and no patient, even if not very refined, cares for that other patient who is so foul and obscene. The first and most pressing need is a sufficiency of single beds for patients disturbing to the ward. It is scandalous that sick people, trying to get better, should have their days and nights made hideous by the worst horrors of illness and death, not to mention obscenity.

On the other hand, the case of the patient who wishes to pay for a single room is one which must be considered, not only because of our oath, but because large numbers will refuse absolutely to go into a general ward—and what are we to do with them? Are we to operate upon them in private houses or shall we have mobile units for operations? Something will have to be done, as the patient is at liberty to refuse to enter a State hospital, and we cannot let them die, even if they do go on strike.

Actually, the State should supply the mobile units free of charge, as the poor have as much right as the rich to refuse to enter a hospital and can more often base their refusal on appalling experiences in the past.—I am, etc.,

Milton.

M. G. H. EDWARDS.

SIR,—The resolution of the association representative of medical officers employed whole-time by the Middlesex County Council (June 1, p. 847), that "the pay-bed system in hospitals should terminate altogether; patients should receive extra privacy, etc., solely on medical grounds" would have come better from an organization that had first passed a resolution that its own members would no longer take advantage of the privacy of side-wards when they themselves are sick, unless, of course, they are afflicted by a malady that demands extra quiet.

If I may spend as I wish when I am well (which seems pretty doubtful), why may I not do so when I am ill? Are invalid luxuries, such as grapes, to be prescribed "solely on medical grounds" by the new medical priesthood?—I am, etc.,

London, W.1.

A. PINEY.

In the Words of Eliza Doolittle

SIR,—Perhaps you will spare me a little more space to reply to Dr. A. S. Barr and Dr. E. Brauer (July 13, p. 67). Let me say at once that I regret having misjudged Dr. Barr's intentions and willingly apologize to him for any unkind assumptions on my part that may not have been justified. However, I still think that the figure of £1,500 quoted by him appeared to be

an essential part of his argument and that it suggested an attempt on his part to prejudge the Spens Report and the probable remuneration under the new health scheme. Despite the advice of the B.M.A. Council, one has heard too many of our colleagues complaining bitterly to the public that the Government intends to grossly overwork and underpay them, and I took this to be another piece of this admittedly bad propaganda. If Dr. Barr had mentioned the figure of £10,000, his whole argument would have collapsed, for I will bet my boots that every member of his Spens Committee would have accepted the job on the spot, door-bell and all.

But surely, Sir, the doctors in industrial districts must partly blame themselves for their conditions and their poor returns for their work. I am not unfamiliar with working-class practice, and there are several ways in which I think they could help themselves, provided always that they can co-operate and not indulge in cut-throat competition. For example: mutual arrangements to "look-out" for one another on half-days and alternate Sundays; evening surgery hours from, say, 5 p.m. to 7 p.m., instead of from 6 p.m. to 8 p.m., or even later; arrangements with local chemists to dispense medicine for their patients; refusal to accept club patients for less than 6d. per week (a sum that can be afforded by anybody except in the case, perhaps, of unemployed persons with large families); the fixing of a reasonable minimum fee instead of the fantastic one shilling, including the medicine, which was the rate in the practice in which I once worked as an assistant; and so forth.

Finally, it may interest many young doctors to know that a few months ago, when seeking a place to settle after being demobilized from the Forces, I was assured by a well-known medical agent that the only hope of making a large income was to go to the industrial Midlands or North. He said that practically all the small practices were in the over-doctored South. The advertisements in the *B.M.J.* certainly suggested that he was right, but I decided on pure air and poverty. However, either the agent or Dr. Brauer must be wrong, and it would be interesting to know if one of the official Spens Committee could enlighten us on the point.—I am, etc.,

Margate.

M. CURWEN.

Psychology in the Child's Education

SIR,—I hope that in his doubts about the wisdom of "teaching the teachers" Dr. Michael Fordham (July 13, p. 62) is referring only to that type of teaching which consists of dogmatic statement. The admitted fact that we, as doctors, have much to learn from the teachers about the child does not in any way controvert the fact that teachers have much to learn from us about the child. Dr. Fordham reminds us that we are "living in glass houses," but if that is so, pulling down the blinds may be as unwise as throwing stones.

The education of the child is society's process of arming and training him for a healthy life in the fullest sense. If that process fails in any respect its failure is in some part the concern of the doctor. An examination system which, by demanding too-early specialization, prevents a child from being educated in accordance with his aptitudes; a worship of "scholarship prestige" which drives the child along an academic route of study when his temperament is far better suited to a practical career; a concentration upon the acquisition of facts rather than upon the development of wisdom and judgment—all contribute their measure to those physical and mental ills which are born of frustration and maladjustment in adolescence and adult life. It is quite clear that some teachers and educationists know these things very well. From the slowness with which such faults are being remedied—even the most recent official pronouncements on the reorganization of examinations go only a short way—we may deduce that the knowledge is not as widespread as it might be. In that case, it is likely that the teachers who "already know" might be helped and encouraged by the knowledge that medical opinion is on their side.

If health be accepted as one of the major aims of life and therefore, as a major aim of social organization, medicine has a duty of social leadership. More urgently, it has the duty to fit itself for social leadership. The doctor must speak, but he must also listen, criticize, and also invite criticism. Let us beware, in Dr. Fordham's words, of "setting ourselves up as authorities in the realm of another profession," but let us remember that the doctor and the teacher are both authorities

the wider field of human well-being. Unless they co-operate fully and in this field, the outlook for the future of social medicine and, we might add, for humanity itself, is most promising.

The issue is an important one, having implications outside the immediate matter of teaching. I would suggest that a large and important part of social medicine is the influencing of social activities in the interests of human welfare, and that this position, "Is it proper for the doctor to assume the role of an instructive social critic?" is one which needs an early affirmative answer from the profession as a whole.—I am, etc.,

Accrington.

JOHN D. KERSHAW.

SIR,—Dr. J. A. McCluskie's letter (July 13, p. 62), which you printed with mine, prompts me to make some further reflections.

It is not, I hope, necessary to draw the attention of our profession to the traumatic incidents, resulting from children going to hospitals, which produce gross psychopathological changes; these are already recorded. We do not, as Dr. McCluskie suggests, want tactful psychiatric treatment of children going in and out of hospitals. What we require is ordinary humanity. According to my experience doctors and nurses in hospitals concentrate so much on getting children physically well that almost all their attention is directed towards this aim. Consequently nobody notices what kind of feelings the child has when his mother comes and goes from hospital, unless they are of the grossest kind. Moreover, the staff are only too often prepared to avoid emotional demonstrations at almost any cost, quite regardless whether the "scene" may be desirable or undesirable for any particular child.

One finds at the end of Dr. McCluskie's letter the somewhat odd statement, presumably derived from Dr. Winnicott's letter, about deliberately keeping children sad. The point at issue is this: so long as children are expressing ordinary human feelings, one of which, though probably the most important, is sadness when their mothers go away, everything is all right in the relationship between mother and child; but directly the ordinary feelings stop then the child is mentally ill. This is something which any average human being could know. These kinds of realities may or not be revealed by statistics and "evidence." They depend on the emotional capacity of the person observing, whether they are seen or not. They are none the less absolutely vital, not only, I would suggest, to the child's mental, but also his physical health.

It seems to me a devastating commentary on medical sophistication that in order to understand simple human feelings it should be thought necessary to do control experiments and collect "evidence."—I am, etc.,

London, N.W.1.

MICHAEL FORDHAM.

The London College of Osteopathy

SIR,—I was greatly surprised, on turning over the pages of the *Lancet*, to find an advertisement inserted by the above college stating that it intended to teach osteopathy to registered medical practitioners. Not so long ago the medical profession, with the help of the British Medical Association, very rightly fought and prevented the official recognition of osteopathy in England, on the grounds that fundamentally the basic principles were wrong and the teaching by the then existing college was inadequate. Presumably the osteopaths have put their house in order, and now, at this time of unrest in medicine through the return of practitioners from the Forces and its transition into State medicine, hope to coax practitioners to take a nine months' course, for which a diploma may be given. The erroneous basic principles of osteopathy are still there.

There are several excellent books on manipulation by British authors. The benefits obtained in certain conditions by gentle manipulation without anaesthesia or the more forcible ones with anaesthesia are well known and practised now by many orthopaedic surgeons and physiotherapists throughout the country. It would appear that the British Osteopathic Association at this stage hopes to gain official recognition by teaching and bringing into its ranks registered medical men. I consider it most important that the medical profession should at this time dissociate itself from this association.—I am, etc.,

London, W.1.

W. E. TUCKER.

Obituary

SIR E. KAYE LE FLEMING, M.D.

Former Chairman of Council, British Medical Association

We announce with deep regret that Sir Kaye Le Fleming died on July 16. He was one of a small group of able men who exercised a decisive influence on the policy of the British Medical Association during those creative years in the interval between the two wars. He had already done much in his own locality, but his voice was first heard in the central council of the Association in the early 'twenties. So evidently was it the voice of a leader that before the middle of that decade he was marked out for high office. For five years he was chairman of the Annual Panel Conference; then after a short interval came his three years' chairmanship of the Representative Body, and this was followed by five years as Chairman of Council, from which he retired at the Aberdeen Meeting just before the outbreak of the last war. His exceptional gifts of leadership were shown alike in the control of large assemblies and in the intimate give and take of small committees, in the shaping of major policy, and in the conduct of routine business.

"E.K." as he came to be affectionately known in this office, was born in 1872, the fifth son of John Le Fleming, an Army coach of Eton House, Tonbridge, Kent, and a greatly-respected figure, known far and wide as the "Preceptor." The establishment was afterwards carried on by the eldest son, John, a famous all-round athlete—double blue at Cambridge, Kent cricketer, footballer, and hockey player, English rugby cap, and figure-skating champion at Davos. Another brother, Canon Hugh Le Fleming, also won fame as an athlete, and in his year was president of the Cambridge team in the inter-university sports. "E.K." himself was a good club cricketer, and in 1894 and 1895 he represented Cambridge at golf against Oxford—a game at which his skill continued for many years. Through his mother, a sister of Sir Ralph Neville, judge of the High Court, Chancery Division, he inherited the lawyer's clear mind and effective speech. His grandfather, Henry Neville, was a surgeon at Esher. The Le Flemings were one of several notable Tonbridge families who excelled at work and games, and "E.K." married into another; his wife was Florence Murton Beeching, daughter of Arthur Beeching, banker, J.P. for the county of Kent.

After a distinguished career at Tonbridge School he won a leaving exhibition and went up to Clare College, Cambridge, in 1891, and having graduated B.A. in 1894 he entered St. George's Hospital. He qualified in 1898, and took his Cambridge medical degrees in the following year. At St. George's he was house-physician and house-surgeon and assistant surgical registrar. Soon afterwards he settled in practice at Wimborne in a partnership of which later he became the head. As at Tonbridge, Cambridge, and St. George's, so in Dorset he identified himself with the life of the place, and soon stood out as a man of mark. His commanding figure and resonant voice were the outward expression of personal qualities above those of the ordinary man.

In Dorset, from the inception of national health insurance—that is, from 1912 onwards—he took a leading part on the Panel and Insurance Committees, and became chairman of the former. Dorset was one of the areas in which conflicting interests sometimes became acute, but "E.K." always bore in mind that the honour of the profession must be maintained and the rights of the insured person safeguarded. In later years he became a member of the Ministry of Health

[Lafayette, Ltd.]

Advisory Committee on national health insurance disciplinary procedure. It need scarcely be said that he filled all the local offices in the British Medical Association. He was in turn honorary secretary and chairman of the Bournemouth Division and president of the Dorset and West Hants Branch.

From this thorough grounding in local administration and policy he went on to take an increasingly important part in central affairs. He joined the Council in 1922, being one of the twenty-four members elected by the Branches of the United Kingdom. In 1924 he was elected chairman of the Annual Panel Conference, and the first of these assemblies over which he presided was also the first to be held in the Great Hall at B.M.A. House. In 1931 he was elected Chairman of the Representative Body, and then in 1934, when the Annual Meeting was held in his own constituency, at Bournemouth, came his unanimous election to the Chairmanship of Council. In accepting office, he said that he was busily engaged in practice and could not promise to devote the time which might be expected of him to the routine work of committees, but he thought it an advantage, as did his fellow councillors, that the chairman should be an active practitioner. In presiding over the Council he showed himself a master in getting through a long and complicated agenda without any sense of hurry or injustice.

When in 1941 the Council resolved to award him the Gold Medal of the Association in recognition of his distinguished work for the B.M.A. and the profession, the address expressed cogently an appreciation of this aspect of his work:

"... First, on occasions not a few you have been called upon, and particularly as Chairman of Council, to represent the Association in public or semi-public, social or intra-professional functions; and again, in more severe service, to negotiate and discuss legislative and administrative proposals with representatives of H.M. Government and other public bodies. Each of these engagements has its own claim and opportunity, and on the verdict of your fellow-representatives you have ever proved equal to the event and have secured a presentation of the Association worthy of its status and traditions.

"Secondly, it is to be observed that while maintaining a high level of interest in the general administrative service of the Association, you have applied a particular attention to developments which offer to the medical profession an opportunity to apply its specialized skill and knowledge to the general welfare of the community, and this both in the prevention of disease and also in the promotion of health. Medicine, you have recognized, is in its widest application a mode of social service which aspires to contribute to the welfare, efficiency, and happiness of the whole body of the people. Particularly in the work of the Association's Committees concerned with Nutrition and with Physical Education you have provided both enthusiasm and direction, and have thus at one and the same time recognized a professional obligation and served well the cause of public policy. That these services have received official recognition is a welcome event to the profession generally, and particularly to those who have been associated with you in various public offices and responsibilities."

His report of the Nutrition Committee in 1935 was widely admired by the general public as an excellent and timely piece of work, and although the credit must be shared by Sir Kaye Le Fleming's hand was felt in it throughout. To the work of the Physical Education Committee he brought initiative, special knowledge, and experience. He himself had been medical officer of Canford School, a large public school for boys at Wimborne, since its foundation. He was also a vice-president of the Medical Officers of Schools' Association, and often contributed to its proceedings. The report of the committee, published in 1936, also attracted widespread attention, and its chairman was made a member of the Medical Advisory Committee to the Ministry of Health on the subject of physical fitness. He was also the representative of the B.M.A. on the Central Council for Recreative Physical Training. A brief mention must also be made of another committee of the Association on which he had long experience, namely, the Parliamentary Elections Committee, charged with the duty of securing, as opportunity offers, suitable representation of medical views in Parliament. Whoever conceived the idea of a Medical Planning Commission, its constitution and terms of reference owed much to Le Fleming's suggestions.

Sir Kaye Le Fleming became a member of the General Medical Council in 1928. He was elected a direct representative for England and Wales, and headed the poll. He was

returned again unopposed in 1933, and was re-elected a few weeks ago for a further term. He sought above all things the welfare of the general practitioner. No doubt he would have had a successful career in any branch of medicine, but he preferred general practice to specialization, and counted himself fortunate to practise in an area which gave him experience of every side of general practice, insurance and private, rural and urban. His *Introduction to General Practice*, published in 1936, summarized his ideas concerning this great primary branch of the profession.

"E. K." had many aspects, all of them engaging. One phase of his personality was seen in business meetings, where he never spoke without illuminating the subject, often swaying the decision. As chairman he was most admirable. Never once in his long series of chairmanships, in the recollection of the writer, did he allow a meeting to get into a difficulty as to procedure. A different phase was seen in his professional work in an old-world country town whose roots went far back into the past. One speaker at a dinner likened him to an ancient abbot of Wimborne presiding over submissive monks. He was a member of the urban district council, had written largely on the history of his county, and was honorary secretary for Dorset of the London Society of Antiquaries. Among his other accomplishments was a considerable knowledge of antique furniture, and with this he managed to combine a zest for so modern a thing as motoring; he was regarded as a pioneer of motoring in Dorset. His active interest in this *Journal*, and the powerful support he gave to its editors over many years, are things that must be recorded with gratitude here. He was a true friend and wise counsellor, constructive in criticism, and openly appreciative of good work.

The honour of knighthood was conferred upon him in 1937. He received the M.D. degree *honoris causa* at Dublin during the Annual Meeting there in 1933, and a like honour at Melbourne, to which he went with the representatives of the Association on the "World Tour" in 1935. The sympathy of all who knew him goes out to Lady Le Fleming and their two sons.

Mr. H. S. SOUTTAR writes:

I first met Le Fleming at Netley in 1917, when we worked together at the Red Cross Hospital, and he stands out in my memory of those days both as a sound physician and a delightful companion. He had a knowledge of the world and a breadth of outlook which were quite exceptional, and I first learnt from him how wide and how deep can be the human interests of general practice. When after the war we met again at the Annual Meetings of the B.M.A. I was still more impressed by his wisdom and his knowledge of affairs. Contact with him was in itself an education in new fields of medical thought, and I am sure that many will feel with me the debt we all owed to his enterprise and inspiration. For years the Association held the chief place in his interest, and he made many sacrifices on its behalf. To its councils he brought dignity and wisdom and a felicity of speech which often carried difficult problems to a happy solution. He was an ornament to his profession, but those of us who had the privilege of his friendship will always remember him as the best of friends.

A memorial service for Sir Kaye Le Fleming will be held at Wimborne Minster on Wednesday, July 31, at 2.30 p.m.

The death of Dr. BINNIE DUNLOP on July 15, at Bracknell, removes an enthusiastic member of the group of social reformers who brought birth control into the foreground during the early years of this century. He was the last surviving son of James Dunlop, M.D., of Glasgow, where he was born in 1874. From King William's College, Isle of Man, he went to the Glasgow High School, and thence to the University of Glasgow. After graduating M.B., Ch.B. in 1898 he was house-physician and house-surgeon at the Victoria Infirmary, and thenceforward interested himself mainly in medical sociology. He served as a civil surgeon during the South African war, and in the latter part of the war of 1914-18 as a temporary captain in the R.A.M.C. From 1913 to 1918 he was treasurer and honorary secretary of the Malthusian League and then became vice-president of the New Generation League; he was also an active worker for the Eugenics Education Society. Dr. Dunlop published the Malthusian essay of 1909 under the title "National Happiness under Individualism," and six years later an article, "The

Efficient Salicylate Medication

'ALASIL' is an analgesic, antipyretic and sedative of established value. It provides the physician with an efficient form of salicylate medication which combines the advantages of high tolerability and greater freedom from the possibility of unpleasant gastro-intestinal sequelæ.

This tolerability is due to the fact that 'Alasil' is a combination of acetylsalicylic acid and Dibasic Calcium Phosphate together with 'Alocol' (Colloidal Aluminium Hydroxide), an effective gastric sedative and antacid.

For these reasons 'Alasil' can be administered with confidence—over prolonged periods if necessary—to children, adults, the aged, and patients with finely balanced digestive capacities.

Each tablet contains 5 grs. Acetylsalicylic Acid, 6 grs. 'Alocol' (Colloidal Aluminium Hydroxide), and 1½ grs. Dibasic Calcium Phosphate.

HUNTS CROSS 1381

DUOCHEM, L'POOL

"truth about Birth and Death Rates," in the *XIX Century*. He contributed to the report of the International Birth Control conference in 1921 and frequently sent notes or short letters to the medical journals. He had been a member of the B.M.A. or 44 years.

Dr. JOHN OSBERT WILSON died at Huntly, Aberdeenshire, on July 16 in his 93rd year. The son of George Wilson, M.D., he was born at Huntly on Aug. 8, 1853, and studied at the Universities of Aberdeen and Edinburgh, graduating M.A. Aberdeen in 1873, M.B., C.M. in 1876, and M.D. in 1878. Settling in practice in his native town, Dr. Wilson became M.O.H. for the burgh of Huntly, joint medical officer to the local cottage hospital, and medical officer to the Alexander Scott Hospital. A keen volunteer, he reached the rank of major, R.A.M.C.(T.), attached to the 6th Battalion Gordon Highlanders, and received the Volunteer Decoration. He was elected a member of the B.M.A. in 1880. In the spare hours of a long professional life he enjoyed angling and the study of local flora and fauna. He received a public presentation on retirement from active work in 1929.

Universities and Colleges

UNIVERSITY OF SHEFFIELD

At a meeting of the University Council, held on July 12, Dr. G. R. Osborn was appointed honorary demonstrator in pathology. The Council received the resignations of Dr. A. Wilson and Dr. J. H. Hale of the posts of lecturer in pharmacology and therapeutics and assistant bacteriologist and demonstrator respectively, and thanked them for their services.

UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated:

M.D.—A. G. Hick.
FINAL M.B., Ch.B.—Part 1: Emma M. H. Albinson, Ruth M. Bowker, G. Castle, Alice M. Clulow, J. P. F. Cook, R. E. Coupland, J. S. Crawford, Charlotte Feldman, R. M. Gaunt, J. A. Gawthorpe, A. E. W. Gregson, Diana J. Haiste, G. B. C. Harrop, R. A. Holman, L. J. Ison, Barbara Jennings, J. R. Jolly, Gladys A. Kitching, A. T. Levine, Evelyn R. Lewis, G. W. Lewis, Ida Mather, D. H. Miller, N. E. Nathanson, B. G. Peet, A. P. Phillips, V. H. Redcliffe, Dorothy P. Russ, J. H. Rust, Catherine M. Rycroft, B. K. Scott, J. H. D. Smith, P. M. Smith, Joan C. Stephens, Elaine M. Sunderland, J. N. S. Taylor, J. D. Thornton, G. C. Turner, L. Vinegrad, Joan L. Walls, H. M. White, G. Wilson.

¹ Distinction in Forensic Medicine. ² Distinction in Public Health.

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examination indicated:

M.D.—F. H. Bentley (with commendation), W. Fielding, F. Fletcher (gold medal), D. Sbuter.

UNIVERSITY OF EDINBURGH

The University Court has received the resignations of two lecturers in the Faculty of Medicine, each appointed to a chair in another university. Robert Walmsley, M.D., senior lecturer in the Department of Anatomy, has been appointed Bute professor of anatomy in the University of St. Andrews; Ian Aird, Ch.M., F.R.C.S.Ed., lecturer in the Department of Surgery, has been appointed to the chair of surgery at the British Postgraduate Medical School, University of London.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The following surgery lectures will be delivered at the college (Lincoln's Inn Fields, W.C.) at 5 p.m. on each day: Oct. 21, Prof. Harry Platt, Localized Cystic Lesions of Bone; Oct. 22, Mr. Geoffrey Keynes, Surgery of the Anterior Mediastinum; Oct. 23, Mr. A. C. Palmer, Aetiology, Symptoms, and Treatment of Procaecidia; Oct. 24, Mr. W. B. Gabriel, Causation and Treatment of Anal Incontinence; Oct. 25, Mr. R. C. Brock, Surgery of Lung Abscess; Oct. 28, Mr. R. J. McNeill Love, Surgery of the Gall Bladder and Common Bile Duct; Oct. 29, Mr. A. E. Porritt, The Value of Penicillin in Surgery; Oct. 31, Prof. Geoffrey Jefferson, Surgery of Intracranial Aneurysms; Nov. 1, Prof. C. A. Pannett, Pancreatic Surgery; Nov. 4, Mr. Terence Millin, Surgery of the Prostate; Nov. 5, Mr. J. B. Hunter, Surgical Treatment of Pulmonary Tuberculosis; Nov. 6, Prof. R. St. Leger Broekman, Intestinal Obstruction.

Fellows and Members will be admitted free of charge, but must apply for a card of admission. A fee of £5 5s. will be charged in the case of others. Tickets may be obtained on application to the secretary.

At a meeting of the Council held on July 11, Sir Alfred Webb-Johnson, Bt., was elected President for the sixth year; Sir Heneage Ogilvie and Sir Cecil Wakeley were elected Vice-Presidents.

Leverhulme Research Scholarships were awarded to Mr. B. W. Rycroft ("The Surgery of Corneal Grafts") and Mr. David Barker, ("The Recovery of Proprioceptor Function after Nerve Injury"), and the seventeenth Maclellin Scholarship was awarded to J. P. H. Davies (Lewes County School).

The following appointments were made for the ensuing year:

Hunterian Professors.—Mr. Guy Blackburn, one lecture on Thoracic-Abdominal Wounds in Modern War; Mr. R. H. Franklin, one lecture on Congenital Atresia of the Oesophagus; Mr. H. A. Haxton, one lecture on Regeneration after Sympathectomy and its effects in Raynaud's Disease; Mr. John Howkins, one lecture on the Movement of the Diaphragm after Operation; Mr. Harvey Jackson, one lecture on the Association between certain Anatomical Facts, Normal and Morbid, and the Symptomatology of Intervertebral Disk Protrusions in the Lumbar Region; Mr. J. B. Macalpine, one lecture on Growths of the Renal Pelvis and Ureter; second lecture on Bladder Growths, with Special Reference to Growths occurring in Workers in Aniline Dyes; Mr. Joseph Minton, one lecture on Occupational Eye Diseases and Injuries; Mr. R. W. Nevin, one lecture on the Surgical Aspects of Intestinal Amoebiasis; Mr. H. W. Rodgers, one lecture on the Post-operative Course of Gunshot Wounds of the Abdomen; Mr. E. R. Smith, one lecture on Intestinal Decompression in the Treatment of Acute Obstructions; Mr. F. G. St. C. Strange, one lecture on the Place of Plastic Procedures in the Preparation of Amputation Stumps for Limb Fitting.

Arris and Gale Lectures.—Prof. Lambert Rogers, one lecture on Ligature of Arteries, with Particular Reference to Carotid Occlusion and the Circle of Willis; Mr. F. F. Rundle, one lecture on the Anatomy of Exophthalmos; one vacancy.

Erasmus Wilson Demonstrators.—Mr. J. T. Chesterman, one demonstration on the Pathological Contents of the Museum, showing Intestinal Obstruction; Mr. V. Zachary Cope, one demonstration on Actinomycosis; Mr. L. W. Proger, two demonstrations; Mr. R. W. Raven, two demonstrations, on (1) Diseases of the Pharynx and Oesophagus and (2) Melanoma and Related Tumours.

Arnott Demonstrator.—Six vacancies held in abeyance pending appointments to the Department of Anatomy.

Diplomas

A diploma of Fellowship was granted to J. R. M. Miller and diplomas of Membership to E. I. Bieber and Janet Sutherland.

Diplomas were granted, jointly with the Royal College of Physicians of London, to the following successful candidates:

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—Ada Barnett, G. V. Blaine, J. A. Campbell, A. H. R. Coombes, A. R. Darlow, J. de Zulueta, K. V. Earle, E. Fletcher, D. W. Gould, Y. G. Gupta, H. Y. Hain, T. H. Harrison, W. Hartston, S. W. Hinds, P. J. Jhaveri, J. W. L. Kemp, W. E. Kershaw, P. M. Lohar, E. A. Lumley, A. McGregor, D. H. Mackay, M. S. Moura, A. H. Mousa, A. K. Ng Chung Hin, P. Rau, H. A. A. Ragab, M. T. Read, A. F. Russell, P. W. J. Searle, B. A. Stoll, Alizon F. Stookes.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—W. V. Bremner; J. C. D. Carothers, G. S. Clouston, J. P. Dewsberry, L. A. Finiels, Joan Fitzherbert, M. Hamilton, W. L. Hardman, H. B. N. Jennings, J. Milne, E. W. Rees, A. P. Russell, Myre Sim, E. D. Taylor, R. L. Whitman, H. G. Williams, W. Warren.

DIPLOMA IN LARYNGOLOGY AND OTOLGY.—R. Barracough, J. C. Delap, H. D. Fairman, S. Gnessen, K. Harrison, L. H. Hiranandani, T. B. Hutton, P. H. Jobson, R. S. McCrea, J. F. O. Mitchell, E. N. Owen, T. A. Quilliam, H. D. Raffan, C. Remington-Hobbs, J. A. Seymour-Jones, H. M. Urquhart, L. E. Wood.

The Services

DEATHS IN THE SERVICES

Lieut.-Col. WILLIAM MAURICE ANDERSON, C.I.E., died after a short illness on July 8 at Hove in his 73rd year. He qualified from the London Hospital in 1897 and entered the Indian Medical Service in 1901. He subsequently took the London M.B. and B.S. degrees, the M.D. in 1904, and also the D.T.M.&H. Cambridge. He served in the 1914-18 war in Persia and Iraq and was twice mentioned in despatches. His work on the civil side was in the political department, during which he held the important appointments of Chief Medical Officer of the North-West Frontier Province in 1920 and Residency Surgeon, Hyderabad, in 1928. He was awarded the C.I.E. for his military service, retired in 1928 and lived at Fleet, Hants. He was a sound all-round medical officer. A member of the British Medical Association for 27 years, he held office as honorary secretary of the Hyderabad branch in 1925-6 and president in 1926-7.

As a token of gratitude for medical attendance to Swedes during the war, Sweden recently presented an x-ray plant to the National Hospital in London. It includes a Swedish invention in this field, a precision apparatus for cranial radiography constructed by Prof. Erik Lysholm, chief of the radiographic section of the Serafimer Hospital in Stockholm, and built by the firm of G. Sebonander.

Medical Notes in Parliament

HEALTH SERVICE BILL

REPORT STAGE

The House went into Committee on recommitment of the National Health Service Bill on Monday, July 22.

On Clause 16 an amendment was agreed to giving the hospital management committees power to carry out research.

On the motion that the clause, as amended, stand part of the Bill, Sir A. HERBERT said that teaching and research were the primary functions of the universities, yet there was no reference to the universities in the clause. This was a highly unsatisfactory situation and the universities took a most serious view of it.

Mr. BEVAN said the universities were in an entirely different position. They could conduct research in their own right, and no one desired to interfere with them. The clause, as amended, was ordered to stand part of the Bill.

A new clause was moved by Mr. KEY. Its object was to enable accommodation to be provided for district nurses and midwives in rural areas. The clause was read a second time and added to the Bill.

FUNDS OF VOLUNTARY HOSPITALS

Commander MAITLAND moved a new clause placing on the Minister of Health the responsibility to ensure that where the need existed hospitals should be provided, during the interim period before their transfer to the State, with sufficient funds to enable them to maintain efficiency. The clause would remove the uncertainty which existed in the minds of those responsible for managing voluntary hospitals. He thought there would be no falling off in subscriptions if it were accepted.

Mr. BEVAN said he had power to assist a hospital that got into difficulties. Everyone wanted to try to foster the enthusiasm and activities of voluntary hospitals in the intervening period before they were taken over, but the House of Commons could not give a blank cheque. There would have been nothing wrong if he had taken all the endowments and used them for general hospital purposes. That was what they were for. Now there was a complaint from Opposition members that in the intervening period before the hospitals were taken over they should be asked to use their money for the reason for which it was given. He had appealed to the voluntary hospitals to try to maintain themselves at maximum efficiency, and to people to continue their contributions to the hospitals. The bulk of the money for the voluntary hospitals came not from the rich people but from the poor, who would maintain their contributions. It was the well-to-do, in some instances, who would not maintain their contributions because the voluntary hospitals were to be taken over by the State. Where voluntary hospitals got into trouble and the efficiency of their service was likely to be impaired by financial conditions over which they had no control, they could come to him and seek assistance. The circumstances of each particular case would be taken into account, but no general promise could be given.

Mr. WILLINK asked if the Minister would disclose from what authority he derived the power to which he referred. Mr. BEVAN said that there were a variety of powers under which it was possible to do this and assured the House that there was no difficulty in the provision of money for hospitals in financial difficulties for reasons over which they had no control. The new clause was negatived by 228 votes to 107. This completed the recommitment stage and the Report stage was begun.

POWERS OF COUNTY COUNCILS

Mr. LIPSON moved a new clause to permit delegation of certain powers of county councils to boroughs within the counties. The powers related to the care of mothers and young children, the employment of midwives, health visiting, home nursing, vaccination and immunization, ambulance service, prevention of illness, care and after care, and domestic help.

Mr. BEVAN said that the new clause would wreck the Bill. If the question of delegation had to be considered before the health authorities, the county and county borough councils, were able to present their schemes, the new health services would not get into operation by April, 1948, possibly not before 1949 or 1950. He agreed that the supervision of the health service must be made as local as possible, but that was already provided for in the Bill. The new clause was negatived by 218 votes to 115.

A long discussion took place on an amendment to Clause 7, moved by Mr. REID, to provide that endowments should not go into a general pool, but should reside in the hands of the hospital management committees set up under the Act. The present proposals of the Government, he said, discouraged

efforts to keep the hospitals going at their fullest efficiency until they were taken over.

Mr. BEVAN said that the money in question could quite properly have been taken by the Government and put into the Exchequer for general hospital purposes. Endowments of teaching hospitals were to be treated separately. If people who had made endowments to particular hospitals could look down on the deliberations of the House they would be very pleased that their benefactions were to serve a wider area of the community.

Mr. WILLINK said that it was obvious that the Government and their supporters were unanimously in favour of the view that there was no harm whatever in diverting funds of donors and subscribers. The Opposition, on the other hand, could see no justification for flouting the wishes of these donors. The amendment was defeated by 249 votes to 107.

Commander GALBRAITH moved the first of a series of amendments to exclude gratuitous covenants from endowments transferred under the Bill. He said that these were moneys which persons had covenanted to pay to voluntary hospitals over a period of years and that it was indefensible that they should be diverted from the purpose for which those who covenanted to give them had intended.

Mr. BEVAN said that at the moment these gratuitous covenants were the legal property of the voluntary hospitals and therefore ought to be transferred along with the other endowments. The amendment was negatived by 255 votes to 110.

L.C.C. AND METROPOLITAN BOROUGHES

On Clause 19 Mr. WILLINK moved an amendment to secure the delegation by the L.C.C. of its functions, relating to certain health services, to the metropolitan boroughs. He said the removal of these functions from the large local authorities without consultation with them was a grossly tyrannical act. It was strange to find the Parliamentary Secretary to the Ministry putting forward views on this matter exactly contrary to those he pressed so strongly in discussions between the metropolitan boroughs and the L.C.C.; the fervid advocacy in public affairs of views which were not one's own was anything but sincere. If the Parliamentary Secretary now expressed surprise, was one to understand that Ministers believed it to be sincere in public affairs to advocate policies in which they did not believe?

Mr. BEVAN said he regretted that Mr. Willink had repeated offensive language he had used in Committee about the Parliamentary Secretary, who was speaking in a representative capacity at the time as chairman of the standing joint committee and was expressing a view he had been asked to put up by his colleagues. Taking into account the shifting population, the problem of Greater London, the creation of new towns, and the establishment of new relations between the local government units, the whole position of the London area was in a state of flux, and one of the main provisions of the Bill should not be changed in order to meet a situation which in the nature of things was bound to be transcended. He was following, in the case of London, the same principle he had applied to the rest of the country, and to make exceptions in London would lay him open to attack from the other authorities. It would be part of his duty to see that as much decentralization as possible was brought in, and it might be that in many places area committees would be a better solution of the difficulties. The amendment was negatived by 224 votes to 99.

Further consideration of the Bill was adjourned.

X-ray Equipment

Asked on July 11 whether the Minister of Supply was aware of the difficulties experienced by hospital authorities in this country in obtaining x-ray equipment, Mr. WILLIAM LEONARD replied that he did not know of a general difficulty in obtaining this equipment. There was, however, difficulty in obtaining replacements for apparatus of German manufacture. Alternative types of valves were now available and the manufacture of tubes was being developed.

Mr. KEY stated on July 11 that it was intended to issue mass radiography plants, as soon as they became available, so as to give a general service to the country.

Health Risks in "Reduxing" Process

Mr. DUMPLETON inquired on July 11 what the Minister of Labour was doing to safeguard the health of workers from the possible harmful effects of new processes introduced into industry without adequate knowledge of their effect upon the health of the workers concerned. He cited the process known as "reduxing" in the aircraft industry. Mr. ISAACS replied that it was the practice of the Factory Department of the Ministry of Labour to keep in touch with new industrial processes and to advise as to any special health risks. "Reduxing" in the aircraft industry was not particularly new. It involved

he use of synthetic resin glues which were known to be liable to cause dermatitis if adequate precautions were not taken. Following inquiries by the Factory Department in 1942 a Departmental leaflet describing the precautions to be adopted is well as a poster for display in factories were widely issued. The main precautions were good ventilation to avoid exposing the skin to vapour from the glue, and measures to reduce contact with the glue and avoid it drying on the skin.

Temporary Registration of Alien Practitioners

On July 18 Sir HENRY MORRIS-JONES inquired on what date the Temporary Registration Scheme for alien medical practitioners expired, and what was the policy of His Majesty's Government in regard to these doctors, particularly those of allied nations.

Mr. BEVAN answered that under the Emergency Laws (Transitional Provisions) Act, 1946, the scheme expired on Dec. 31, 1947, unless the relevant Defence Regulation was revoked earlier by Order in Council. Future arrangements were under consideration and it was not yet possible to make a statement on the subject.

Panel Patients and Osteopaths

On July 18 Mr. HOUSE asked whether Mr. Bevan was aware that Mrs. C. Barker, 118, Fairview Road, Penn, was refused a medical certificate by her doctor on the ground that she attended an osteopath without the doctor's permission, and she thereby lost benefit from her friendly society.

Mr. BEVAN said he knew of the doctor's refusal to issue a medical certificate in this case. An insurance doctor was under no obligation to issue a medical certificate to a patient who was obtaining treatment from some other person without his consent.

Diphtheria Immunization

In reply to Mr. PETER FREEMAN on July 18 Mr. BEVAN said returns from local authorities in England and Wales showed that between January, 1940, and June, 1945, diphtheria notifications and deaths, respectively, numbered 19,040 and 142 among immunized children, as compared with 141,600 and 3,635 among children not immunized. Of some six million children immunized in England and Wales 14 cases had come to notice of later illnesses in the possible causes of which the diphtheria prophylaxis could not be positively excluded as having had no part. He knew of no evidence to support the suggestion that children who had been immunized proved more subject to other diseases in later life.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales an increase in prevalence was recorded for measles 347 and whooping-cough 174, with a decrease in scarlet fever 66, dysentery 36, and diphtheria 23.

The increase in the notifications of measles in the counties surrounding London continued; the largest rises were Essex 77, Warwickshire 60, Surrey 55, and Kent 54. In London itself 69 fewer cases were notified than in the preceding week.

The only large rise in whooping-cough was 80 in Yorkshire West Riding. The decline in scarlet fever was confined to the southern part of the country, and the largest fall was London 36. Variations in the trend of diphtheria were decreases in Durham 14 and Middlesex 10, and an increase in Yorkshire West Riding 12. The notifications of dysentery were the lowest for over three years. The only county where more than 8 cases were reported was Lancashire with 21.

An outbreak of food-poisoning has affected persons in the Witham, Braintree, and Maldon districts of Essex. A full account appears at page 131 of this issue.

Five cases of poliomyelitis have been reported from Potters Bar, Middlesex. The patients are all school-children and were attending four different schools.

In Scotland a fall was recorded in the incidence of measles 143 and whooping-cough 30; rises were reported for diphtheria 18 and dysentery 15. The increase in diphtheria was contributed by the western area, despite a decrease of 9 in Glasgow.

In Eire the chief feature of the returns was a rise of 22 in the incidence of measles. There were 6 more cases of diarrhoea and enteritis in Dublin C.B. than in the preceding week.

In Northern Ireland the notifications of measles fell by 19.

Week Ending July 13

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 845, whooping-cough 2,270, diphtheria 277, measles 3,981, acute pneumonia 416, cerebrospinal fever 33, dysentery 61, poliomyelitis 12, paratyphoid 17, typhoid 6.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 6.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Medical News

The King has made the following promotions in and appointments to His Majesty's Household: Mr. A. E. Porritt, Surgeon to the Household, to be a Surgeon to the King; Mr. R. Marnham, to be Surgeon to the Household; Sir Reginald Watson-Jones, to be Orthopaedic Surgeon to the King; Mr. C. S. Morris, Surgeon-Dentist to the King, to be Sergeant Surgeon-Dentist to His Majesty; and Mr. A. C. R. McLeod, to be Surgeon-Dentist to the King.

The 25th annual general meeting of the Medical Society for the Study of Venereal Diseases will be held at 11, Chandos Street, W., to-day (Saturday, July 27) at 2.30 p.m. The presidential address will be read by Dr. G. L. M. McElligott on "The Management and Treatment of the Late and Latent Syphilitic." A discussion will follow.

There will be a clinical meeting of the Medical Society of the L.C.C. Service on Thursday, Aug. 8, at 3 p.m., at Hammersmith Hospital and Post-Graduate Medical School, Du Cane Road, Shepherd's Bush, W.12. Cases will be demonstrated by the staff of Hammersmith Hospital.

A special series of lectures, conferences, and demonstrations in clinical and laboratory medicine will be held at the Hospital de la Santa Cruz y San Pablo at Barcelona from Oct. 5 to Dec. 21. Copies of the programme printed in Spanish may be had from the director of the hospital, Dr. F. Gallart Monés.

The political committee of the Constitutional Club on July 18 entertained to lunch Dr. Charles Hill, Secretary of the British Medical Association, and Lt.-Col. J. Lockwood, Conservative candidate for Bexley. After lunch Dr. Hill spoke to members of the club on the National Health Service Bill. The chair was taken by Sir Herbert Williams.

The Duchess of Portland, speaking at the annual meeting of the National Association for the Prevention of Tuberculosis, stated that a tuberculosis survey in the West Indies had just been completed, and a most interesting report published. The Association had appointed Dr. Kenneth Waller Todd to make a similar survey in the Gold Coast Territory. More research, education, and propaganda were needed, especially in the smaller colonies, and the N.A.P.T. was ready to play its part.

The following Ministry of Health appointments took effect from Jan. 1, 1946: Principal Medical Officer in charge of Epidemiology and International Health, Dr. M. D. Mackenzie; Principal Medical Officer in charge of the Insurance Medical Service, Dr. R. E. Whitting; Principal Medical Officers, Drs. C. F. Good, T. S. McIntosh, E. L. Sturdee, T. W. Wade (Welsh Board of Health); Senior Medical Officers, Drs. A. L. Banks, N. R. Beattie, W. H. Bradley, E. Donaldson, C. J. Donelan, R. E. Ford, G. E. Godber, N. M. Goodman (*in absentia*), G. C. Kelly, C. T. Maitland, F. N. Marshall, H. A. Raeburn, W. D. Hopkins, A. E. Huxtable, E. Martin, R. O. C. Thomson.

Higher salaries in a wide range of hospital nursing posts, including matrons, and in the public health service—in all for nearly thirty grades—are recommended by the Rushcliffe Committee. Concessions are also proposed where trained nurses have returned to nursing from the Forces, or where male student nurses have resumed their training after war service. With the recommendation of these increases the Rushcliffe Committee's current review of nursing salaries is almost completed. The Minister of Health has welcomed the new scales and recommended their adoption to the employing authorities. Salary increases are retrospective from January 1 last.

The Newcastle and North-east Branch of the Socialist Medical Association has issued as a 6d. pamphlet a report on Tuberculosis on Tyneside with suggestions for remedying the high incidence of this disease there. Copies can be had from 43, Albury Park Road, Tynemouth.

A Bill to create a mental health institute is under discussion in the United States Senate. The institute is planned as a research and training centre for a broad attack on mental disease problems which have been detected through recent research, especially during the war.

In recognition of his studies upon chemotherapy in tuberculosis the College of Physicians of Philadelphia has awarded the Alvarenga Prize for this year to Dr. William H. Feldman, of the Mayo Foundation for Medical Education and Research. The College usually makes this award for outstanding work and invites the recipient to deliver an Alvarenga Lecture.

Miss E. Alden, deputy chief nursing officer of the Ministry of Health, has been appointed to represent the Ministry as a member of the Central Midwives Board for England and Wales which is responsible for carrying into effect regulations of the Midwives Acts.

Dr. Norman C. Parfit has been appointed deputy medical adviser to the Central Council for Health Education.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Althology* *Westcent*, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate*, *Westcent*, London. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra* *Westcent*, London.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Gonococcal Vulvo-vaginitis

Q.—A girl of 6 developed a gonococcal vulvo-vaginitis three years ago. She had several courses of sulphonamides and two one-day courses of penicillin (100,000 units). A swab taken one month ago showed no gonococci but many pus cells and staphylococci. The discharge is yellow, profuse, and offensive. Antiseptic douching has proved of no avail. What general and local treatment would you advise?

A.—First, the presence of gonococci should be established or excluded by repeated smears and cultures; a complement fixation test for gonorrhoea might be helpful, especially if positive. All these pathological examinations should be carried out in a laboratory which normally deals with such specimens. Two other possible causes of the vaginitis should be investigated—*Trichomonas vaginalis* and *Oidium albicans*; the former can be most easily demonstrated by means of the dark-ground microscope.

Treatment will depend on the results of the pathological examinations. If gonococci are found a further course of penicillin extending over forty-eight hours is indicated. For trichomonas vaginitis the best remedy is stavarsol, insufflated in powder form or as pessaries inserted high up in the vagina. For vaginal thrush painting with 1% gentian violet solution is recommended; this may be done through a short male urethroscope. In general, dry swabbing and painting with a mild antiseptic, such as 2 to 5% mercurochrome, are preferable to douching. As a last resort, oestradiol may be given by injection, 4,000 to 5,000 units daily. General treatment should include fresh air and an adequate diet with milk, fresh fruit, and vitamins. Tonics may help, and iron should be given if the child is anaemic.

Symptoms due to Glass-fibre Wool

Q.—Some patients of mine, working on a new fabric made from glass, complain of dryness of the mouth and a tickling sensation in the throat. Occasionally, minute splinters of glass still adhere to the fabric. I am unable to detect any abnormality in the mouth or pharynx. Is there any danger of fibrosis of the lungs due to inhaling dust from the fabric, and would it be advisable for these workers to wear masks?

A.—Nothing is known of harmful effects from the new fabric made from glass; but it might be assumed to be similar to glass-fibre wool. This substance is highly irritant and is known to produce dermatitis and symptoms similar to those mentioned. The irritant effects are caused by tiny pieces of glass. Glass is a silicate, and information is not available to prove that it is harmless to the lungs. Animal experiments were carried out with the dust from glass-fibre wool, but no disease in the lung resulted, probably because the particles were too large to enter the alveoli. It would be wise, however, to take precautions, and if the workers will wear masks it would be good for them to do so.

Drinking at Meal-times

Q.—Is there any evidence whatever in favour of abstinence from drinking at meals?

A.—There is no scientific evidence in favour of abstinence from drinking at meals. The point to remember is that the fluid ingested will dilute the chyme in the stomach; the existence of a *magenstrasse*, or physiological short cut for liquids

aving the stomach, has not been confirmed by recent experiments. The drinking of moderate amounts of water with meals tends to increase the secretion of digestive juices and to promote digestion. Handbooks of dietetics commonly recommend that a glass of water should be drunk before or during each meal. Fluid at meal-times is only harmful if it is taken in too great bulk, if it is iced or otherwise irritating, or if it is used to wash down unchewed food. The suggestion that the drinking of normal amounts of fluid at meal-times is harmful may be a misconception, due to the fact that patients with a weak digestion are sometimes recommended to take a large tumblerful of warm water, with a quarter- to half-teaspoonful of baking soda at a half an hour before meals to stimulate the flow of gastric juice.

Mammary Duct Infection with Staphylococci

Q.—What is the best treatment, and the outlook, as regards breast-feeding for a primigravida, in the thirty-sixth week, from whose mammary ducts yellow pus containing *Staph. aureus* can be expressed?

A.—Two counter-questions naturally arise: (1) How is it known that the organisms are in the fluid as it comes from the ducts and not merely contaminants from the skin of the nipple? (2) Has it been verified microscopically that the fluid is pus and not colostrum, which looks purulent? If it be established that *Staph. aureus* is present in the ducts without local inflammatory reaction, then the finding is not of great significance. Little is known of the occurrence of *Staph. aureus* in the ducts during pregnancy, and investigation is difficult for the reason implied in (1) above. However, it is probably not uncommon, for it has been shown to be present in the colostrum in a small percentage of cases on the first day after delivery, in the milk in about 50% of cases by the end of the first week, and in an even higher percentage by the tenth or eleventh day. The organisms as a rule do not appear to be pathogenic to either mother or child—unless the milk is stored without provision for inhibiting bacterial growth before being given to the baby.

On the other hand, if there is in this case a local inflammatory reaction in the breast and the discharge is purulent, caution is necessary. There would then be a risk of staphylococcal infection of the baby, and presumably an increased likelihood of breast abscess in the mother. In such circumstances efforts should be made now to clear up the infection. Probably this would be best achieved by the administration of penicillin systemically, and also locally to the nipple and surrounding skin. Preliminary penicillin sensitivity tests on the organisms are desirable.

Menopausal Headaches

Q.—A woman of 47 had severe headaches up to a year ago. Her periods then ceased and the headaches almost disappeared. The periods started again a few months ago and so did the headaches. What would be a useful line of treatment?

A.—It is impossible to make a definite diagnosis on the somewhat meagre data. In particular, it would be useful to know whether the headaches bore any relationship in time to menstruation. Pre-menstrual headache is a common complaint, and is apparently in many cases related to fluid retention. Such cases should be treated by a low salt diet for the week preceding menstruation. A diuretic should also be given—e.g., urea—one heaped teaspoonful of the crystals three times daily. As the patient is 47 years of age and is already on the verge of the menopause, it might be worth while to consider inducing an artificial menopause by means of radium.

Penicillin in Pyorrhoea

Q.—Is penicillin of any value in the treatment of pyorrhoea?

A.—The chronic and subacute types of gingivitis, loosely classified together as "pyorrhoea," usually show pocketing of the gum round the teeth with active infection at the base of the pockets. The majority of oral pathological organisms are sensitive to penicillin, and the types found at the bottom of these pockets are no exception. It follows, therefore, that organisms can be eliminated from the pockets with penicillin. The pockets themselves, however, remain. Experience has shown that after a course of penicillin treatment the condition recurs unless the pockets are dealt with mechanically—e.g., by gingivectomy, cautery, etc. In the acute forms of gingivitis, penicillin is of

great value, though here again on subsidence of the acute symptoms attention must be directed to eliminating foci by mechanical means. Penicillin is most conveniently employed in the mouth in the form of pastilles or lozenges containing 500 units each, the high diffusibility of the drug necessitating a slowly dissolving medium. For further information see *British Medical Journal*, 1944, 2, 686.

Sites for Intramuscular Injection

Q.—With the increasing use of penicillin, which may mean 50 or more intramuscular injections in the course of six or seven days, a choice of sites for injection is particularly important. Please describe how intramuscular injections can be given with safety into the buttocks, thighs, deltoids, and interscapular region.

A.—**Buttock.**—Injections are often made close to the tuberosity of the ischium into what is thought to be the thickest part of the gluteus maximus muscle. The curve of this part of the buttock is produced largely by fat, there is less thickness of muscle than elsewhere in the buttock, and the course of the great sciatic nerve runs dangerously close to the site of injection. The accompanying sketch shows that in relation to the great sciatic nerve the safe area of the buttock lies above a line joining the top of the greater trochanter of the femur to the third sacral spine. The latter usually lies deep to the top of the natal cleft, but its position can be checked by finding the second sacral spine at the level of the line joining the two posterior superior iliac spines. It is a good plan to mark this safety line on the skin with dye or a skin pencil when injections have to be given by assistants who have not had much experience of the technique. Just above the junction of the middle and posterior thirds of this line is the optimum spot.

Thigh.—Intramuscular injections may be given with safety into the lateral aspect of the upper two-thirds of the thigh, as all the important structures lie medial or posterior to the femur and out of harm's way. Injection here is usually more painful than in the buttock.

Deltoid Region.—Although injections in this region can safely be made by an experienced person, it is not a suitable site for routine use when deep injection is required. Near its insertion the deltoid muscle becomes too thin for an injection to be made without giving an unnecessary amount of pain. In the upper and more fleshy part of the muscle there is a risk of damaging the circumflex nerve, or of making the injection into the shoulder joint. Distal to the deltoid insertion the radial nerve is in danger.

Interscapular Region.—This site would be chosen for injection only when circumstances forbade the use of the more suitable areas. The injection should be made into the sacrospinalis (erector spinae) muscle. The risks of going too far laterally and entering the chest, or too far medially and entering the subarachnoid space may easily be avoided by the expert, but must not be run by those with little knowledge or experience. Furthermore, even in expert hands, an injection given in this area must surely be more uncomfortable for the patient than injections made in almost any other part of the body.

In conclusion it may be said that experience shows the safe area of the buttock to be far and away the best site in the body for intramuscular injections.

Tests for Smallpox

Q.—The public health authority at Padua use a "rabbit test" to decide the diagnosis in doubtful cases of smallpox. What is this test? How reliable is it? How much significance has a negative result?

A.—It is difficult to be dogmatic on what is meant by a "rabbit test," but in the absence of fuller details it could be regarded as the old Paul's test¹ in which the contents of variolar pustules, after drying, were applied to the scarified cornea of the rabbit. This test is not now considered reliable, and a negative result should be regarded as inconclusive. The name, however, could be applied, very loosely, to the precipitation or complement-fixation test in which vesicular or pustular fluid or extracts of scabs are used as the antigen and an immune rabbit serum as the antibody. The results, of the complement-fixation test particularly, are highly reliable; a diagnosis should stand or fall on this test. In cases where the diagnosis is in doubt the questioner might obtain valuable help from Van Rooyen and Illingworth's technique.² Scrapings of papular or vesicular material are smeared on clean glass slides and stained by Paschen's method; the elementary bodies of variola are much larger than those of herpes or varicella. Here again, however, a negative result does not rule out smallpox.

INCOME TAX

Car Transactions

J. C. proposes to sell car "A" and buy another car "B" at a net cost of £800—"B" is presumably not a car of superior quality to "A" when the latter was bought. Can he treat the £800 as an expense against his income as a consultant? The car is used entirely for professional purposes.

* There appears to be no legal bar to treating the transaction in that way, though in the long run it would seem preferable not to do so, but to claim in due course the new "initial" and depreciation allowances against the gross cost (£1,400) of car "B."

J. M. resumed consulting medical practice after Army service on December 14, 1945, and will discontinue it as from September 1, 1946, when he will become a whole-time salaried employee. In preparing an income tax statement covering the 8½ months to September 1, how should he treat the following transactions? Car "A" was bought on December 14 for £495 and sold on June 12, 1946, for £357. That car ceased to be used as from March 17, 1946, when car "B" was bought for £390.

* If a single account is prepared J. M. can choose between (a) charging the cost of renewal as an expense or (b) claiming depreciation. The claim under (a) would be to deduct £495—£357=£138.

The claim under (b) would be as follows:

Car A. £495 at 24% for 3 months, i.e., ¼ of £119, i.e., £30.
Car B. £390 at 24% for 5½ months, i.e., 11/24 of £94, i.e., £43.

Total for both cars £30+£43=£73.

As an alternative, J. M. might consider preparing two accounts, one for the period to April 5, 1946, and the other for the remainder the 8½ months. As the latter would be the final account of the practice, and as car B would be deemed to have been acquired April 6, 1946, an "initial" allowance as well as the depreciation allowance could then be claimed in respect of car B.

Car Expenses of Assistant

"ASSISTANT" started work in an appointment as from Dec. 1, 1945, in a wide rural practice. He needs the use of two cars, one of which, however, is also used by his wife.

* As "ASSISTANT'S" liability for the year from April 6, 1947, will ultimately be dealt with on the actual year's basis, the allowances he will be entitled to (subject to some adjustment in view of the partial use by his wife) are: (a) a wear-and-tear allowance at 25% on the written-down value of each car as at April 6, 1946; (b) an "initial" allowance at 20% of cost in respect of the car bought in February, 1946, but, for the purposes of this allowance, regarded as having been bought on April 6, 1946; and (c) the usual running expenses including repairs, insurance, tax, etc. To avoid excessive deductions we advise our correspondent to prepare an estimate of these amounts and send them to the local tax office—or call with them—and ask for a modification in his code number for 1946-7, pending a more precise ascertainment of his assessable income at the end of the year.

"Cash Receipts" or "Earnings" Basis

M. C. dissolved partnership on April 1, 1945, and practises on his own account. The partnership was assessed to tax on the basis of cash receipts, but the inspector of taxes refuses to agree to the new practice being dealt with on that basis.

* The inspector is legally justified, and is following the usual method in dealing with a new practice. The reason is that in such circumstances the cash received in the first two or three years of the practice are an inadequate index of the real gross earnings. It is admittedly difficult to estimate the value of outstanding medical debts, but the inspector will presumably agree to M. C.'s estimate if done to the best of his ability.

LETTERS, NOTES, ETC.

Artificial Pneumoperitonium

Dr. S. C. COLUECK (Jersey) writes: In the answer to the question on artificial pneumoperitonium (June 22, p. 974) one sentence—"Others feel that the procedure has certain limited indications—for instance, for the treatment of cavitating lesions situated in the lower lobe, especially in its dorsal segment, or in the treatment of acute pneumonic tuberculosis"—is too misleading to go unchallenged. If the mechanics of respiration are considered in conjunction with the anatomical configuration of the thorax it will be realized that the upper half of the thorax is a comparatively fixed structure that relies almost entirely on the up and down movements of the diaphragm for its respiratory excursions, whereas the mobility of the lower half of the chest wall with its 2 to 4 in. (5 to 10 cm.) of circumferential expansion is in the main responsible for the aeration of the lower areas of the lung fields. From anatomical considerations, and from clinical and radiological results, diaphragmatic paralysis with or without pneumoperitoneum gives more relaxation and rest to the upper lung areas than it does to the lower.

While on the subject of thoracic anatomy, I would like to refer to a clinical sign that still occurs in modern text-books—Grocco's triangle. If anyone will take the opportunity to study drawings of the thorax in cross-section, and take note of the spinal column and paravertebral muscles in relation to the pleural spaces, the lung fields, and the mediastinum, they will be struck by the realization that Grocco's triangle should be, and is, percussible as an area of dullness bilaterally on normal subjects, as well as on patients with a contra-lateral pleural effusion.

Medical Terminology

Dr. C. J. EARL writes from Guy's Hospital: All those who use medical language to try to express their thoughts accurately will agree that in many fields of medicine the terminology may be very confusing. We must admit, of course, that much of this confusion arises because we are uncertain in our own minds about the exact nature of the condition we set out to describe or classify. Anyone who tries to master the classification of nephritis, for example, will realize this at once. There is, however, another cause for this confusion, which does not operate only where our knowledge is deficient; it is the unhappy, if well-meaning, enthusiasm of some of our teachers and authors for inventing new names for conditions already often well defined and well named. The inventor will regard his new name as more apposite, descriptive, or easily remembered. Usually, however, the old name lingers on, and the new name is but slowly universally adopted, so that for many years, and maybe even for ever, the last state is very much worse than the first. It is for this reason that I think the section on causalgia in the latest edition of *Price's Textbook of Medicine* deserves comment. It is there suggested, on the grounds that in causalgia the pain is of a burning nature, that we call the condition "thermalgia." Now has the author of this suggestion forgotten that the word causalgia is derived from the Greek *αλγος*, meaning pain, and *καλο* (Aorist *εκαυσα*), meaning I burn? I think he might well have consulted his dictionary before suggesting an alternative which, though he thought it described the condition more accurately, will serve only to increase the burden which the seeker after knowledge must carry in his mind.

The Itchy Patient

Dr. J. W. HAUGHTON (Truro) writes: In the excellent article by Drs. H. MacCormac, P. H. Sandifer, and A. M. Jelliffe (July 13, p. 48), there is no mention of diabetes being a possible cause. I was an itchy man for twelve months. Itching very severe on legs and serotum. Tendency to incontinence. My urine was loaded with sugar. Friend I consulted modified my diet—and the sugar and itching ceased.

"Burning Feet": Correction

Dr. HUGH S. STANNUS writes: In my letter in your issue of July 13 (p. 63), by a slip of the pen, I mentioned folic acid. This should of course have been pantothenic acid. I apologize for this error.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 27 1946

INSURANCE ACTS COMMITTEE OF THE B.M.A.

REPORT OF SPECIAL MEETING

INSURANCE CAPITATION FEE

Minister's Offer of 12s. 6d.

A special meeting of the Insurance Acts Committee was held on July 22 to consider an offer by the Minister of Health, orally communicated to the committee's representatives on July 17, of an increase in the capitation fee to 12s. 6d.—that is, an increase of 2s.—with retrospective effect from January 1, 1946. Before proceeding to the business of the meeting a silent tribute was paid to the memory of the late Sir Kaye Le Fleming, former Chairman of the Panel Conference, of the Representative Body, and of the Council.

Dr. E. A. GREGG, who presided, said that the representatives of the committee had met the Ministry, as instructed, and had pressed the claim for an increase in the capitation fee for insurance practitioners, urging in support of the claim the statement in the report of the Spens Committee (*Supplement*, May 18, p. 143) that the remuneration of doctors in general in 1939, was up to £200 a year below (on average £170) what it should have been. This deficiency should be considered wholly in relation to the insurance income. Taking the 9s. pre-war capitation fee, which the profession considered to be much too low, this addition would have brought it up, on pre-war standards, to between 12s. and 13s. To this had to be added a betterment factor to meet the change in values. Although 2% was considered low, it was the figure which had been discussed in other connexions, and if this low figure were applied it would yield a capitation fee of somewhere in the neighbourhood of 15s.

Dr. Gregg went on to say that the Minister had been present at the first discussion, but generally his point of view appeared to be that he wanted to wrap up the question of the immediate capitation fee with discussions on the remuneration of doctors under the proposed new National Health Service. To this, of course, on a number of grounds they could not agree, and they came away from that first meeting extremely dissatisfied. They were, however, invited to go again, but once more it was argued on the part of the Ministry that the question of remuneration under the new service must be regarded as having a hearing in the settlement of the insurance capitation fee in the interim period. The representatives of the Insurance Acts Committee took up the position that they were not authorized to enter into any discussions or haggling in relation to the new service; the terms and conditions appertaining to the new service were matters on which the profession as a whole would have to be consulted, and indeed the profession had already expressed a strong view on the method of payment to be adopted—they were opposed, for example, to basic salary. The point was still pressed upon the Ministry that there was no reason why questions relating to the future service should be tied up with this immediate issue of an increase in the capitation fee, which was acknowledged as long overdue.

At the third meeting an offer was made of an increase in the capitation fee to 12s. 6d., which was regarded as wholly inadequate. In making their original claim they had urged that the increase should operate as from January 1 of this year. This was at first opposed by the Ministry, and indeed the Minister himself actually suggested that the increase should not operate until January 1, 1947, a suggestion to which strong objection was taken. Ultimately the offer was made that the increase be retrospective from January 1, 1946, and this, the Ministry's spokesman said, was equivalent to a capitation fee of 13s. 1d. as from July 1. The representatives of the committee

pointed out that if it had been found that the true increase was 13s. 1d.—still an entirely inadequate figure—the conditions which made the increase suitable applied just as much to January as to July.

The Minister and the Spens Report

It was on this oral offer that the present meeting was called, but that day, within an hour of the meeting, the following letter had been received from the Ministry:

"Dear Dr. Hill,

"The Minister has asked me to refer to the recent meetings between his officers and representatives of the profession and in particular to the meeting held on Wednesday last with representatives of the Insurance Acts Committee about the remuneration of doctors within the National Health Insurance Scheme during the period before the proposed National Health Service comes into operation.

"The principal factor in any consideration of this question and of the question of remuneration in the future health service is the report of the Spens Committee on the Remuneration of General Practitioners. The Minister desires to make his attitude to that report quite clear. He fully accepts the substance of the recommendations of the committee in their majority report upon the general scope and range of remuneration which general practitioners should enjoy in a public service. The actual terms of remuneration cannot, however, be calculated from the recommendations by a simple process of arithmetic; the calculation involves consideration of a number of factors (e.g., the effect of a superannuation scheme and the percentage of betterment to be applied to pre-war figures) which are matters for discussion.

"The Minister is consequently of opinion that the translation of the Spens recommendations into actual terms of remuneration—whether for the new health service or for the present health insurance scheme—is a matter which must be discussed with the profession. Moreover, in his view, it must be discussed as a whole; it is impossible to divorce the question of the current capitation rate from that of remuneration under the new health service since some of the problems to be examined affect both questions. He learnt, therefore, with regret of the feeling among your representatives that they are not authorized to discuss the terms of remuneration in the future health service now. He would have assumed that they could do so expressly without prejudice to the profession's subsequent general attitude to the National Health Service proposals, just as other representatives of the profession recently discussed the question of amounts of compensation without prejudice to the future attitude of the profession to the proposal to abolish the sale of practices in the public service. He still trusts that on further consideration your representatives will be willing to take part in the wider discussions which he for his part is prepared to begin at once.

"If, however, the profession's representatives adhere to the view that they cannot do this, the Minister is left with no alternative but to defer discussion. In the meantime, he is prepared to increase the current capitation rate by an amount which appears to him to be reasonable. He therefore proposes to raise the present capitation fee to 12s. 6d. and in addition to regard this rate as having been operative since January 1, 1946.

"Yours sincerely,

"(Sgd.) WM. S. DOUGLAS."

Dr. Gregg added that Sir Wilson Jameson, who was in the chair on the occasion of the last meeting, had used the term "interim payment," which most people would interpret as a payment on account, but whether it meant much or little he could not say. The word "interim" did not appear in the letter quoted above, but the phrase "in the meantime" appeared in the penultimate sentence, and might possibly bear the same meaning as "interim."

"Gravely Inadequate"

The committee then embarked upon a long discussion on the Minister's offer and its implications. Every member of the committee gave his views, and several gave the views, so far as it had been possible to gather them, of other practitioners in the different localities. It was the unanimous opinion that the proposed increase was gravely inadequate. It was pointed out that the Spens Committee had made proposals approximately equivalent to the augmentation of net incomes in 1939 by £200 over a large income range, and that if this augmentation were spread over the entire profession it would mean an average annual increase of £170 for each practitioner. The argument of the committee on this point had been that as the rate of remuneration from private practice was under the control of the practitioner, whereas that from insurance practice was not, the deficiency should be considered as appertaining to the insurance side of the practice. Dr. J. A. BROWN, who was a member of the Spens Committee, said it was abundantly clear that, if not the whole of the £170, at all events very nearly the whole, should be regarded as belonging to the insurance side.

The Secretary (Dr. CHARLES HILL) pointed out that in the different interviews there had been no commitment by the Ministry to the acceptance of the Spens Committee's findings, but in the letter now received from the Ministry it was stated that the Minister "fully accepts the substance of the recommendations of the [Spens] committee in their majority report upon the general scope and range of remuneration which general practitioners should enjoy in a public service." The Chairman of Council (Dr. DAIN) said that the Minister had intimated that he was not prepared to discuss at all the effect of the Spens Committee report so far as concerned the insurance capitation fee, but that he was prepared to discuss the terms and conditions of doctors in the new service, and when these were determined, to consider their bearing upon the new capitation fee. The representatives who met him had explained that they represented the Insurance Acts Committee only, and had no authority to negotiate any terms or conditions in a service which had not yet come into being; and there a disappointing interview terminated.

In a later interview with Ministry officials they found the same insistence that the implications of the Spens Committee report must not be considered except in relation to the new service, a position they could not accept.

In a very long and frank discussion, in which various forms of resolution were proposed, these were withdrawn in favour of a resolution proposed by Dr. J. A. IRELAND as follows:

"That the Minister be informed that the Insurance Acts Committee, while it welcomes the Minister's acceptance of the majority report of the Spens Committee and his recognition of the inadequacy of the capitation fee, regards the proposed increase of the capitation fee to 12s. 6d. as gravely inadequate."

This was carried unanimously.

The Next Step

Discussion then took place on the next step. Some members took the view, on a careful reading of the letter, that the door was not closed to further conversations. The chairman pointed out that any new approach must be accompanied by some counter-suggestion, expressing willingness to accept some body to which the controversy might be referred. The body which suggested itself as the most fitting for such a reference was the Spens Committee. The alternative would be the acceptance of some form of arbitration. Many members of the committee spoke in favour of the Spens Committee resuming its activities for this special purpose. On the other hand some question arose whether constitutionally the Spens Committee could properly function in this respect. On this point, however, Dr. TALBOT ROGERS drew attention to a letter from the Ministry of Health to the Association, dated May 17, 1944, when the suggestions which led up to the formation of the Spens Committee were brought forward by the Ministry. One passage from the letter read as follows:

"It seems to the Minister that what is required is to approach the whole subject afresh and with a clear field, and in co-operation with the profession to set on foot an inquiry by a small independent committee which would arrive at useful general standards, on which future arrangements between the profession and the Minister could be confidently founded. . . . It is realized that while the proposals

of the White Paper on a National Health Service are under discussion with the profession and others, it is not possible to anticipate what exact form any public general medical practice may take in the future, or what will be the terms and conditions on which practitioners are invited to take part in it. But in the Minister's view this does not affect the desirability of an early inquiry of the kind just indicated, the results of which would not prejudice the discussions of the White Paper at all, and would be equally valuable and usable no matter what forms of public medical practice may continue or may come into being under the present law or under any future legislation."

It was felt by the committee that this letter effectually disposed of the claim that the Spens Committee findings could be considered only in relation to the projected new National Health Service.

Resolutions were tentatively put forward by members of the committee. Dr. W. D. STEEL proposed that the Committee should express the opinion that the capitation fee should be at least 15s., retrospective to January 1, and that if this was not agreed to by the Minister steps should be taken to consult all insurance practitioners concerning future action.

The chairman suggested that in sending to the Minister the resolution already adopted it might be stated in a covering letter that this subject had received the very closest attention of the Insurance Acts Committee, and that certain matters had emerged in the course of discussion which they desired at a further meeting to place before the Ministry. The Minister might then be informed of the desire of the committee that the Spens Committee (which he could reconstitute without requiring further legislative sanction) should look into the matter, and that both the Minister and the Insurance Acts Committee should abide by its findings. That would be a clean-cut issue, and if the Minister refused they could then meet again and decide as to the summoning of a Special Panel Conference. The letter of May, 1944, would be brought to the attention of the Minister, and those who represented the committee would continue to insist that the present capitation fee must be considered on its own, quite divorced from any sort of fee which might obtain in the new service.

Claim for 15s.

After further discussion, a resolution was proposed to the committee, and Dr. Steel and others withdrew their wordings in its favour. It read as follows:

"That the Minister be informed that the Insurance Acts Committee would be prepared to recommend insurance practitioners to accept in the interim a capitation fee of 15s., retrospective to January 1, 1946. The committee would be willing, if the Minister so prefers, that the Spens Committee should be asked to state the implications of its majority report in relation to the current insurance capitation fee on the understanding that the Minister and the Insurance Acts Committee accepted, in advance, the findings of that Committee."

This also was carried unanimously, and a meeting which had lasted almost three hours terminated.

Correspondence**The Bill and the Capitation Fee**

SIR,—The most important fact facing the medical profession as a whole to-day is the matter of the N.H.I. capitation fee. The amount of the payment for the value of practices has already been decided upon and has been calculated on the capitation fee at its present level. Soon the payment of doctors' salaries will be determined. It is to be by capitation payment and will no doubt be influenced by the present capitation fee. The Winchester division have forwarded a motion on this subject for the next conference. We should remember, however, that the inadequacy of the capitation fee has been before the Insurance Acts Committee continuously for at least twenty-five years, and for twenty-five years they have failed dimly to effect any appreciable alteration. They have been to the Minister time after time with an excellent case and have been told they can have no more. What next? The matter is then dropped and raised again at the next conference. The Winchester division is merely continuing this hopeless cycle.

All through the last few years useless discussions have been taking place in respect of the new Health Act, when any other

ganization would have pressed for adequate payment before any discussion of any kind were held. The tendency in industry to-day is to pay 5½-day wages for a 5-day week, but we must still carry our 7-day week, with no increase in pay. When I raised the question of the capitation fee at a meeting some months ago, I was answered by an official of the B.M.A. that this would be dealt with immediately after the publication of the Spens report. Why has nothing been done now? Why is it necessary to have the matter on the agenda again and again with more and more delay? Surely the time has come for some other body to deal with this question. Cannot the divisions of the B.M.A. elect another body, led by adequate counsel, who would at least have the courage to hammer the matter out until a proper fee has been obtained? Have all the country doctors forgotten how Dr. Williams Freckman, acting alone, obtained the country practitioners' mileage grant when the Insurance Acts Committee had failed, as usual, so miserably?—I am, etc.,

Reading.

S. C. ALCOCK.

* The Ministry's reply to the repeated representations of the Insurance Acts Committee for an increased capitation fee will be found in the report of a special meeting of that committee at page 31 of the *Supplement*.—Ed., B.M.J.

A Good Augury

SIR,—Much correspondence has been written about the evils of State control of medicine, and the cold hand of officialdom as been referred to at times. May I be permitted to give my own experience with the nearest approach we have had so far—the National Health Insurance Scheme? In 1942 I was elected for service with the armed Forces, and I communicated with the clerk of the London Insurance Committee. He invited me to go and see him, and I was surprised at the kindness shown to me. Nothing appeared to be too much trouble to help me, and in one matter the clerk went much beyond what I need do in meeting my wishes.

Since then on several occasions I have found the same unailing courtesy and kindness, and I wish to place on record my gratitude to him. I have no connexion with the committee in any way, except as one of numerous "panel practitioners." If this is an augury for the State service, it is a good one.—I am, etc.,

CHARLES F. STOTT.

Rehabilitation

SIR,—I was much interested to read the report of the committee on rehabilitation (June 29, p. 187). I note that at the end of Section I (para. J) the committee ask for details of other facilities available for rehabilitation. I have recently become the medical officer of an industrial concern which is specializing in this form of work. This consists of a woodwork factory started by individual initiative and from a real social conscience in order to provide facilities for rehabilitation. It is taking 75% of disabled cases, class I and II, and providing employment for them at trade union rates. The cases consist of all types, both civilian and Service, and range from psychological disabilities to severe war injuries. The following condensed reports may give some idea of the range of cases:

B.S. 56.—Congenital heart with patent septum. Lengthy history of psychological difficulties resulting, finally, in complete dereliction.

B.S. 49.—Post-encephalitic Parkinsonism confined to one side. Injuries as test pilot.

B.S. 42.—Shrapnel in the right foot (Sicily 1943) resulting in very painful scars, and ankylosis of ankle joint from septic arthritis.

B.S. 44.—Rheumatic fever after 11-mile route march before D-Day. Psychological difficulties.

B.S. 47.—Blind.

B.S. 52.—Epileptic. Muscular cramp due to previous occupation in iron foundry, holding heavy objects in tongs all day.

B.S. 41.—Epilepsy.

B.S. 43.—Diabetes. Liability to hypoglycaemic attacks.

B.S. 48.—Psychological difficulties. Repeated treatment in psychological clinics and hospitals. Hyperhidrosis of hands—can be followed by trail of drops of sweat on the floor.

B.S. 50.—War injury to spine in Navy.

B.S. 55.—Bronchitis and asthma.

B.S. 57.—Both legs amputated.

This brief cross-section of some of the cases should give a fairly clear indication of the type of material. The medical

team consists of a psychologist, a trained physiotherapist, and myself. Frequent consultations are held between us and the managing director to ensure co-operation and a unified approach to the problems which arise. The foremen have been specially chosen for qualities of sympathy, tact, and ability to handle men of this type. They are kept informed of the medical aspect of each case and given special instructions by the medical team. The psychologist, in addition to taking full psychological histories, including periods of unemployment, making psychological tests and giving interviews, will also, where necessary, visit the homes of patients as a psychiatric social worker. Full reports are being obtained from medical attendants and hospitals.

The managing director and administrative personnel also work in the factory and make a first-hand study of the difficulties encountered by the workers. Everything is avoided which can give any suggestion of charity and the emphasis is laid on the desire of each individual to support himself by doing a worth-while job. The management invites inspection by members of the Rehabilitation Committee at any time.—I am, etc.,

London, N.W.3.

T. GLADSTONE.

Doctors' Houses

SIR,—I should like to point out to "Ex-Service Assistant" (*Supplement*, July 13, p. 12) that "colossal premiums asked for doctors' houses" are due to the colossal prices asked for any house. If a retiring practitioner were to sell his house for a pre-war price he would have to pay twice as much for a mere cottage—if he could get one. Even retired people have to live somewhere.—I am, etc.,

South Godstone.

H. E. GIBSON.

Association Notices

Meetings of Branches and Divisions

EXETER DIVISION

A general meeting of the Exeter Division was held on June 23 at the Royal Devon and Exeter Hospital, with Dr. J. D. Murray in the chair. The Annual Report of Council for 1945-6 (*Supplement*, April 20) was considered, and the chairman asked members if there was any clause to which they wished to draw particular attention. Dr. Richard referred to clause 65, relating to cost of living bonus to pensioners, and Dr. Eager, supporting this clause, hoped that representatives would do all in their power to ensure that this should be granted. Dr. Murray, referring to clause 66 (National Maternity Service), noted that the Royal College of Obstetricians and Gynaecologists had refused to modify in any way the conditions under which it was prepared to grant its diploma. He said that anxiety was felt lest, as a result of this, doctors who had been practising midwifery for a considerable time would be debarred from that work in spite of being authorized to do so by virtue of their position as qualified doctors. The meeting endorsed Dr. Murray's hope that strong representations would be made. On clause 75 (Education Act) concern was expressed at the different rates of pay for school children in hospital which were laid down by the education authorities and the health authorities respectively. The fees offered by the education authorities of one guinea for the first week and 1s. 6d. a day subsequently were held to be inadequate; they had been accepted only as a wartime measure and patriotic gesture. It was thought that the payment should be not less than one and a half guineas for the first week and 4s. 6d. a day for subsequent days. Dr. Roper drew attention to the point that no arrangements had been made for non-domiciliary treatment by general practitioners, but that after representations it had been agreed that a fee of 5s. per attendance would be authorized.

MALAYA BRANCH

With the return of many members of the B.M.A. to British Malaya, and on account of numerous inquiries from Asiatic members whose membership was in abeyance during the Japanese occupation, an effort is being made to reconstitute the Malaya Branch. The Northern Division (hon. secretary Dr. R. K. Ponniah, General Hospital, Penang) has already held its first meeting with an attendance of 20. A few clinical cases were shown and a discussion as to the business of the Division was held. The Division has agreed to meet monthly. The Southern Division has also held a meeting, but so far no report has been received. The F.M.S. Division (now styled Central) is holding a meeting soon. The object is to elect office bearers, and discuss ways and means of bringing the Divisions up to their former strength.

The Council of the Malaya Branch has, through the depredations of war, not yet been reconstituted, but the President-elect (Dr. J. W. Winchester), the hon. treasurer (Dr. Lee Choo Neo), and the hon. secretary (Dr. R. E. Anderson) have been working together to establish the Branch again. As many members have changed their

addresses, or have got out of touch with the Association, the hon. secretary is anxious that they should communicate with him (Dr. R. E. Anderson, Health Office, Kinta District Board, Ipoh).

MORPETH DIVISION

A meeting of all members of the profession in the area of the Morpeth Division was held on June 14.

A report on the activities of the Local Medical War Committee during the year 1945-6 was given by its chairman, Dr. H. Skinner Brown. The constitution of that committee in its present form was approved. The meeting then elected the members of the Local Medical War Committee to be appointed by the whole profession: Dr. T. S. Blacklock and Dr. A. B. H. Irvine. Members elected by the Executive Committee of the Division: Dr. W. Stephenson and Dr. G. R. Spence. Member elected by the M.O.H.: Dr. C. B. McGregor. Representatives of the medical staffs of hospitals, municipal and voluntary, in the area: Mr. A. A. Bonar and Dr. G. Stenhouse. Proposed representatives of the Local Medical and Panel Committee: Dr. H. S. Brown and Dr. M. Maclean. It was resolved that further members be co-opted by the above committee if considered necessary.

Dr. Brown then proposed a vote of thanks to Dr. Spence for his valuable services and expressed the appreciation of members for the large amount of conscientious work which Dr. Spence had carried out in the interest of the Division since he took up his duties as honorary secretary. This was passed with acclamation. After some discussion it was decided that the Executive Committee should meet at an early date and draw up a programme of meetings and lectures for the winter of 1946-7.

A meeting of members of the Morpeth Division was held immediately after the above meeting. An address was given by Mr. A. A. Bonar on the uses of penicillin in general practice. Dr. McGregor described her experience of the use of a penicillin spray in the treatment of diphtheria carriers. Some discussion followed. Dr. Willbur C. Lowry then showed two films dealing with the discovery, preparation, and methods of use of penicillin and the methods of detecting the sensitivity of various organisms to penicillin.

Temp. Acting Surg. Lieut.-Cmdr. (R.N.V.R.) A. J. Barrett and Temp. Surg. Lieuts. (R.N.V.R.) R. St. C. Mooney, D.S.C., A. C. Hamer, N. S. Marsden and R. W. Simpson have been transferred to the R.N. in the rank of Surg. Lieut.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Cmdr. E. E. D. Gray has been placed on the Retired List. Temp. Acting Surg. Lieut.-Cmdrs. J. H. Burkinshaw, D. W. Wallace, A. C. C. Hughes, and J. H. E. Summerhill to be Temp. Surg. Lieut.-Cmdrs.

Temp. Surg. Lieuts. T. G. Williams, H. S. Provis, A. B. Pollard, and R. S. P. Hawkins to be Temp. Surg. Lieut.-Cmdrs.

ARMY

Col. R. W. Galloway, C.B., C.B.E., D.S.O., late R.A.M.C., to be D.D.M.S., and has been granted the acting rank of Major-Gen. Col. E. B. Marsh, M.C., late R.A.M.C., to be Acting Major-Gen. Col. H. A. Sandiford, M.C., K.H.P., late R.A.M.C., has retired on retired pay and has been granted the honorary rank of Brig. Col. F. C. K. Austin, late R.A.M.C., having completed four years in the rank, is retained on the Active List supernumerary. Lieut.-Cols. E. Underhill and J. M. Macfie, C.B.E., M.C., from A.M.C., to be Cols. Lieut.-Col. A. E. Richmond, C.B.E., from R.A.M.C., to be Col. (Substituted for the notification in a *Supplement* to the *London Gazette*, Nov. 19, 1945.)

ROYAL ARMY MEDICAL CORPS

Major-Gen. O. W. McSheehy, C.B., D.S.O., O.B.E., to be Col. Comdt.

Lieut.-Cols. P. J. Ryan, M.C., and G. T. Garraway have retired on retired pay, and have been granted the honorary rank of Col. Major (War Subs. Lieut.-Col.) J. M. Ryan to be Lieut.-Col. Major G. F. Harrison to be Lieut.-Col.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

War Subs. Majors W. G. Love and J. B. Bishop to be Majors.

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

War Subs. Capt. (Miss) M. D. W. Hamilton has relinquished her commission on account of disability, and has been granted the honorary rank of Capt.

War Subs. Capt. (Mrs.) H. Polakova has relinquished her commission.

B.M.A. LIBRARY

The following books were added to the library during May and June, 1946:

- Albee, F. H., Powers, E. J., and McDowell, H. G.: *Surgery of the Spinal Column*. 1945.
- Bailey, H.: *Demonstrations of Operative Surgery for Nurses*. 1946.
- Bailey, H., and Lovc, R. J. McN.: *Short Practice of Surgery*. Seventh edition. 1946.
- Bockus, H. L.: *Gastro-Enterology*. Vols. 1, 2, and 3 and General Index. 1946.
- Brown, W.: *Personality and Religion*. 1946.
- Burrows, H.: *Biological Actions of Sex Hormones*. 1945.
- Cawadias, A. P.: *Hermaphroditos: the human intersex*. 1946.
- Christopher, F. (Editor): *A Textbook of Surgery*. By American Authors. Fourth edition. 1945.
- Crile, G., and Shively, F. L.: *Hospital Care of Surgical Patients*. Second edition. 1946.
- Drinker, C. K.: *Pulmonary Edema and Inflammation*. 1945.
- Dubrisay, L., and Jeannin, C.: *Précis d'Accouchement*. Tenth edition. 1945.
- Fothergill, C. F.: *A Doctor in Many Countries*. 1945.
- Gigon, F.: *The Epic of the Red Cross or the Knight-Errent of Charity*. 1946.
- Gley, E.: *Traité Élémentaire de Physiologie*. Tenth edition. 1942.
- Gurd, F. B., and Ackman, F. D.: *Technique in Trauma: planned timing in the treatment of wounds including burns*. 1945.
- Haynes, W.: *This Chemical Age: the miracle of man-made materials*. 1946.
- Honig, P., and Verdoorn, F. (Editors): *Science and Scientists in the Netherlands Indies*. 1945.
- Iselin, M.: *Chirurgie de la Main*. 1945.
- Jackson, C., and Jackson, C. L. (Editors): *Diseases of Nose, Throat, and Ear, including bronchoscopy*. 1945.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

- BROWN.—On July 13, 1946, to Kathleen, wife of James L. Brown, M.D., R.A.F.O., of 95, Hornby Road, Blackpool, a daughter.
- KELLY.—On July 16, 1946, at the Royal Cornwall Infirmary, Truro, to Susanna (née Findlay), wife of Dr. John Kelly, Isles of Scilly, a son.
- KENYON.—On July 11, 1946, in Manchester, to Dr. Marjorie Landau, wife of R. H. Kenyon, F.R.I.C., a daughter.
- RADCLIFFE.—On July 7, 1946, to Lilian, wife of Anthony Radcliffe, F.R.C.S., 15, Wimpole Street, a son.
- WILSON.—On July 9, 1946, at Spinners Wood, Sevenoaks, to Mary (née Silva), M.R.C.S., L.R.C.P., and Major J. Michael Wilson, R.A.M.C., a son.

MARRIAGES

- DORNHORST-INNES.—On July 8, 1946, in London, Antony Clifford Dornhorst, M.D., M.R.C.P., to Helen Mary Innes, M.B., Ch.B., D.M.R.
- SARGENT-SCOTT.—On July 4, 1946, Frank Sargeot, M.D., M.R.C.P., D.P.M., to Mary Margaret Scott.

DEATH

- CRICHTON.—On July 20, 1946, at Inverbrothock, Redhill, Crawford Smith Crichton, M.D., Edin., M.B., Ch.B., the dearly loved husband of Barbara and devoted father of Elizabeth, Ann, Robert, Susan, and Richard. Age 64 years.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 3 1946

BRITISH MEDICAL ASSOCIATION

ANNUAL REPRESENTATIVE MEETING, LONDON, 1946

PRESIDENTIAL ADDRESS

MEDICINE IN TRANSITION*

BY

Sir HUGH LETT, Bt., C.B.E., F.R.C.S.

Consultant Surgeon to the London Hospital

I propose to begin my address by briefly reviewing the work of our profession during the anxious and exacting years of the war. It will not be possible to do more than outline some of the most outstanding features, but they will serve to show how great this work was and how much this country owes to its medical men and women, and to the profession as a whole.

Medicine During the War

When we speak of war our thoughts by reason of our training dwell first on the casualties, the wounded, and the sick. I will therefore begin by discussing the treatment of the wounded, the proportion that survived, and the extent to which they regained their full capacity. The final statistics are not yet published, but we know enough to realize that they will show a remarkable improvement over those of the first world war. Brigadier Philip Wiles,† for instance, has told us that in the M.E.F. during the year April 1, 1942, to March 31, 1943, the over-all mortality rate was only 2.1%, which is less than one-third of the rate in Egypt and Palestine during the previous war. No less striking is the very large proportion of the wounded who recovered completely and were able to return to their units.

These results must be mainly attributed to the work done by our medical scientists on the sulphonamides and allied preparations, and more recently the discovery of the value of penicillin, but important contributing factors were the establishment of the mobile field surgical units and the admirable organization for the collection and disposal of casualties, which enabled the wounded to be treated with so little delay. Perhaps only those who served in the last war and remember the extent and severity of suppuration in the wards, the long and often painful convalescence of so many of the wounded, and the number of amputations that had to be performed, can fully appreciate the change that has taken place. Then again, the science of blood transfusion has made great progress, and due credit must

be given to those who by their work in the laboratory and in the field were instrumental in saving many thousands who without this treatment would have had little chance of recovery. Among other surgical triumphs the intensive study of rehabilitation has enabled large numbers to return to a life of full activity who in the last war would have been permanently and often seriously handicapped by their injuries.

If we turn to Medicine we find that in this war, as in the last, preventive inoculation, combined with chlorination of water supplies, almost eliminated typhoid, which was such a scourge in the South African War, when among the relatively small forces employed there were 59,750 cases, with 8,227 deaths. With the help of the sulphonamides the mortality of cerebrospinal meningitis fell from the high proportion of 50-70%, which obtained in the previous war, to 10% in this, and in some outbreaks to as low as 4%. Nor can we forget the triumph over typhus through immunization and the use of D.D.T.

In the early stages of the campaign in South-East Asia tropical diseases took a heavy toll and presented a very serious problem. A special word of praise is due to those who solved it and brought the prevention and control of these diseases to such a high level that they made a great contribution to the success of the campaign. I need only recall the speech of Admiral Lord Louis Mountbatten at the Guildhall on July 10, when he said that to the discomfort of the Japanese, who had no remedy against these diseases, he deliberately chose unhealthy areas in which to fight. It would be difficult to imagine a greater tribute to the work of the Medical Services.

I have of necessity to omit much that should be mentioned and must pass over much of the valuable work that was done at home by the E.M.S., by the rank and file of the profession, and by the medical officers of health. I cannot, however, omit reference to the Central Medical War Committee and its laborious task of classifying all the doctors on the *Register* and keeping the lists up to date. In addition it undertook the responsible work of making

* A brief address on his election to the Presidency of the Association at the Annual General Meeting on July 24.

† *Lancet*, April 22, 1944.

nominations for the Services with the help of the Committee of Reference and the local Medical War Committees. This was arduous and most difficult, for, while the Committees had to meet the tremendous demands of the Services, they had to keep constantly in mind the needs of the civil population and at the same time to give sympathetic consideration to cases of special hardship. All these things make a worthy record, and the profession may well feel proud of what it has achieved.

The Royal Colleges and the B.M.A.

As we review the last seven or eight years we cannot overlook the close relations that have developed between the Royal Colleges and this Association. Until shortly before the war each pursued its own path; each was concerned almost entirely with its own affairs, and there was no regular channel of communication between them.

In 1938, however, when the Committee of Reference of the Royal Colleges in England, originally appointed in the first Great War, was revived, a move was made to put an end to this isolation. Dr. Anderson, then Secretary of the Association, was invited to serve as liaison officer between this Committee and the Central Medical War Committee, and it was decided to hold meetings in the house of the Association. As the late Chairman of the Committee of Reference, I gratefully acknowledge the courtesy of the Association in providing the accommodation, and its generosity in placing its secretarial department at the disposal of the Committee.

Then in 1940 the Association invited all the Royal Colleges to join with it in reviewing the peacetime organization of the general medical and hospital services, to consider how far they were satisfactory and how they could be made more efficient. After a little negotiation the invitation was accepted and the Medical Planning Commission was formed. This was a historical event. For the first time the various bodies met together in common council to debate matters in which all members of the profession were concerned.

When, therefore, the last Government published its White Paper on a National Health Service the profession as ready and prepared for discussions with the Minister

Health, and the Negotiating Committee arose almost automatically from the Medical Planning Commission.

Lastly, the President and Council of the Royal College of Surgeons invited the Association to send a representative to attend the meetings of the College Council. Dr. Guy Dain was nominated and received a warm welcome.

Critical Days

These are critical days, and this increasing co-operation must give satisfaction to those who look ahead and see the dangers that may arise from State control over the profession in their care of the sick.

The high standard of British Medicine and its prestige are due in no small measure to the freedom the profession has hitherto enjoyed: a freedom unfettered by the trammels, the frustrations, and the infinite delays of bureaucracy, and, above all, a freedom untouched by the ebb and flow of politics.

The care of the sick is an art as well as a science. Medicine is not a plumbing job, nor is it as simple as building houses. Men and women are not robots—they

are sentient human beings, varying in their constitution and in their response to different forms of treatment. Each patient is an individual with his own temperament, foibles, likes, and dislikes; each needs sympathetic understanding and encouragement. If we are to maintain our ideals, if we are to continue to regard our patients as individuals and not merely as cases and types of certain forms of disease, if we are to preserve the invaluable confidential relationship between doctor and patient, the freedom of the profession in clinical matters must be preserved. Research must be encouraged in every possible way, but it is to be remembered that money alone cannot bring results, nor have all men the temperament and mental qualities it demands: discoveries are not made to order. Most important is the fact that successful research is a rare and delicate plant which flourishes at its best only in an atmosphere of freedom.

In the uncertain months and years that lie ahead it is vital that the medical profession should be united and able to speak with one voice; otherwise it cannot hope to have the influence that is essential if the interests of the sick are to be safeguarded to the full and the members of the profession are to have proper consideration. Every effort, therefore, must be made to maintain and develop the close relationship that now exists between the Association and the Royal Colleges. Each body has its own province. The Royal Colleges are concerned with the promotion of the art and science of medicine, surgery, obstetrics, and gynaecology, and they are responsible for the growth of their branch of learning both directly and through their Fellows on the councils of the universities. On the other hand, there is much that can be done only by the British Medical Association. It has rendered great services to the profession, and its task has not always been easy. In such a democratic body criticism is of course inevitable; but constructive criticism is always welcome: it is a valuable corrective and strengthens the whole system. The Council must be gratified and encouraged by the rapid increase in the membership of the Association, which has grown from 38,000 in 1938 to 52,000, and now represents some 80% of the profession. It is to be hoped that it will grow even stronger and ultimately include all British medical men and women.

Constant Vigilance

I have drawn attention to the high standard of Medicine in this country and have mentioned some of the great achievements of our medical men and women during the war. Now, however, that Medicine has been dragged into the turbulent sea of politics the future is obscure. Steeped as we have been in the great traditions of our profession since we first entered the wards of our teaching hospitals, some of us may feel that we can afford to smile at the little minds and loud voices that decry us and accuse us of being self-seeking obstructionists. But constant vigilance will be necessary, and, for this reason the present happy co-operation between the Association and the Royal Colleges should be permanent and not allowed to lapse when the immediate emergency has passed. It is only by working together, consolidating our profession, and making it as strong as possible that we can protect the sick and maintain the proud position of British Medicine, together with all those things tangible and intangible for which it stands.

PROBLEMS ARISING FROM THE USE OF PENICILLIN IN GONORRHOEA

BY

R. C. L. BATCHELOR, F.R.C.S.Ed. W. H. DONALD, M.B.

AND

M. MURRELL, F.R.C.S.Ed.

From the Edinburgh Corporation and Royal Infirmary Department of Venereal Diseases

Among the problems which have arisen from the penicillin therapy of gonorrhoea are the following: (1) Can the multiple- (five or ten) injection technique used so successfully in the Services be superseded in civilian out-patient practice by a "one-shot" or a "two-shot" method? (2) Does the dosage of penicillin used in the treatment of gonorrhoea "mask" the presence of a concomitantly acquired syphilis, or does it not? (3) Is there any danger that the single-injection method of treatment, if it should fail, will produce a penicillin-fast strain of the gonococcus? (4) Is it advisable to give irrigation when penicillin is used?

Articles that have recently been published show that among those engaged in treating venereal disease there are very decided differences of opinion on these questions. For example, Allan (1946) describes the apparently completely successful use of a single-injection method (dose 200,000 or 300,000 units) in a small group of thirty cases of gonorrhoea, and expresses the hope that "in some clinic dealing with large numbers, and where patients can be under more continuous supervision, the single-injection method will be tried out on enough cases to provide accurate statistics." Allan states that "the single-injection method has several demerits"—for example, "the danger of producing a penicillin-fast strain of the gonococcus" and "the very real danger of masking an early syphilis"—and in this latter connexion he stresses "the necessity for regular serological tests for the following twelve months." On the other hand, Marshall (1946), in commenting on Allan's pronouncements, states that he has "not yet seen any cases where syphilis became evident later than three months after penicillin therapy for gonorrhoea and without another exposure to possible infection." Marshall remarks that "it would be interesting to have . . . reasoned opinions . . . on the length of follow-up necessary after the treatment of gonorrhoea with penicillin in the doses now used."

Various Injection Techniques Compared

The efficacy of multiple-injection techniques in gonorrhoea, either untreated or sulphonamide-resistant, has been emphasized by Harrison (1945), who recommended five 2-hourly doses of 30,000 units, and more recently by Lées (1946), who adduced a cure rate of 98% in 344 sulphonamide-resistant cases treated with ten 3-hourly doses of 10,000 units. Marshall (1945) has stated recently that "the best method of treatment of gonorrhoea with penicillin . . . is with doses of not less than 100,000 units given intramuscularly in four or five separate injections at 2-hourly or 3-hourly intervals over a period of 8-12 hours." On the other hand, from the point of view of civilian practice, multiple-injection techniques have distinct drawbacks, and a "one-shot" or "two-shot" method much more nearly approaches the ideal. But is it practicable by only one or two injections to achieve a cure rate comparable to the high efficiency of the five-injection plan? Romansky and Rittman (1944) have shown that a single dose of 100,000 units could be highly effective when its action was delayed and prolonged by suspending the penicillin in peanut oil containing 2 or 3% of beeswax. Lloyd Jones *et al.* (1946), using suspensions of penicillin containing magnesium sulphate to delay absorption, have described a one-injection method which achieved apparent cure in 95.6% of 113 male out-patients. In the hope of arriving at a satisfactory minimal-injection technique, various methods have been tried in groups of cases at the Edinburgh clinic, and the results recorded are shown in Tables I and II.

Certain cases were considered unsuitable for a one-injection or a two-injection technique, and for these a multiple-injection

method was used; these cases fell into one or other of the following groups: those with metastatic complications, such as arthritis and iritis; those with local complications, such as abscess of the prostate gland in the male or abscess of Bartholin's gland in the female; young girls with gonococcal vulvo-vaginitis; and babies with gonococcal ophthalmia. In one of these cases chosen for multiple-injection treatment—that of a little girl of 4 suffering from gonococcal vulvo-vaginitis—the gonococcal infection showed amazing persistence after what constituted a colossal dosage of penicillin even for this resistant type of case. First of all this child was given fifteen 3-hourly intramuscular doses, each of 20,000 units, which resulted in an apparent clearing-up and temporary disappearance of gonococci from the smears. But slight redness and discharge returned and gonococci reappeared in the smears, so another course of twenty-four 3-hourly doses, each of 20,000 units, was administered. Again there was temporary improvement, and thereafter again recurrence. A third course was now given, comprising sixty 3-hourly doses each of 40,000 units, and, after the usual improvement, again relapse occurred. By this time the child had received no fewer than ninety-nine intramuscular injections of penicillin to a total dosage of 3,180,000 units—more than enough to cure most cases of sero-negative primary syphilis in an adult—and still the gonococcus had not been beaten. In pity for the little patient the idea of still more penicillin was abandoned; instead recourse was had to the sulphonamides, and 15 g. of sulphadiazine caused disappearance of signs and gonococci, though the period of observation has not been long enough to justify claiming a cure.

Tables I and II show in comparison the results obtained by one-shot and two-shot techniques.

TABLE I.—Results of Giving One Single Intramuscular Injection of 200,000 Units

	Period of Investigation	Nature of Preparation	No. of Cases	No. of Relapses	Cure Rate %
Male cases:					
Group 1 . .	June, 1945, to Feb., 1946	Saline solution without adrenaline	135	31	77.0
" 2 . .	July, 1945, to Oct., 1945	Saline solution plus adrenaline	103	20	80.6
" 3 . .	Nov., 1945, to Dec., 1945	Oil-beeswax suspension	41	4	90.2
Female cases:					
Group 1 . .	July, 1945, to Jan., 1946	Saline solution without adrenaline	35	4	88.6
" 2 . .	July, 1945, to Dec., 1945	Saline solution plus adrenaline	58	7	87.9

TABLE II.—Results from Two Intramuscular Injections, Each of 200,000 Units

	Period of Investigation	Nature of Preparation	No. of Cases	No. of Relapses	Cure Rate %
Male cases . .	Jan., 1946, to April, 1946	Saline solution	190	8	95.8
Female cases	Jan., 1946, to April, 1946	Saline solution	55	5	90.9

Description of Preparations Used

All solutions of penicillin were made up with sterile normal saline, the usual concentration being 200,000 units of the sodium salt dissolved in 4 or 5 ml. of saline. The beeswax-peanut-oil suspensions contained 2.5 or 3.5% beeswax, and the strength of the suspension was 50,000 units per ml.

In the group of cases in which adrenaline was used to prolong the action of the penicillin by delaying absorption and

excretion, 2 minims of 1 in 1,000 solution of adrenaline hydrochloride were added to and mixed with the penicillin solution in the syringe, the adrenaline being used in an attempt to prolong the bacteriostatic concentration of penicillin in the blood according to the method suggested by Fisk, Foord, and Alles (1945). In the second group of cases, which received two intramuscular injections, the second injection was given six to eight hours after the first. With this scheme it is necessary for the patient to report for treatment twice in the same day. So far it has been possible for every patient to arrange to do this. In the event of a person's reporting for the first time in the evening, for the sake of consistency, and to avoid having to give a second injection in the middle of the night, the first injection might be deferred till the following morning. There is, however, an obvious risk in delaying treatment, and it is, on the whole, probably better in these cases to use a single-shot technique, and repeat it the next morning if smears still show gonococci.

Method of Administration, and Tolerance

All injections were made intramuscularly into the upper outer quadrant of the buttock, and when two injections were given both buttocks were used. As a rule the intramuscular injections were well received by the tissues. Reaction, expressed by pain, swelling, redness, and induration, varied with the make and batch of penicillin used, and was apparently due to impurities, being most evident where the sample was dark brown in colour and of low penicillin content, and very slight with light-yellow samples of greater purity and potency. In most cases the local intolerance was negligible, and, in the few where local pain and stiffness were encountered, these were not of an incapacitating nature.

General intolerance has been minimal, though in a few cases faintness, nausea, pallor, sweating, and rapid feeble pulse occurred after the injection. It is thought that in most instances this was psychological, and due to the prick of the needle rather than to the action of the penicillin solution. The majority of the patients exhibiting these features occurred in the series receiving 2 minims of adrenaline in addition to the penicillin, and in these the untoward effects might have been due to the rapid absorption of the adrenaline. This was a transient phenomenon and passed off quickly without special treatment.

Relapses

A certain number of cases in each series had received previous treatment with sulphonamides and some had been treated with penicillin. Those which had received previous sulphonamide treatment were neither more nor less liable to relapse on the dose of penicillin given than those which had had no previous treatment. In each series 91% of the males had no urethral discharge the second day after treatment. The duration of the discharge depended on the severity of the infection before treatment was instituted; in only 2.4% of the male patients did it persist for more than three days.

11 cases which relapsed on the initial dose of penicillin—where the urethral discharge persisted or returned (usually within 14 days) and was found to contain gonococci—were cured by further treatment with penicillin, usually by one of the methods using multiple injections of saline solution at 3-hourly intervals. A few of these relapse cases were cured by a course of 25 g. of sulphathiazole or sulphadiazine given in five days.

All cases reported have been under observation for at least two weeks after treatment with penicillin. Most of them have been under observation for some months, and several have been observed for six months and discharged as cured.

Concomitant Syphilis

Five of the male patients in the series now reported on, and two additional males, have during their period of observation developed syphilis, and, so far as has been ascertained, infection with *Sp. pallida* took place at the same time as infection with the gonococcus. In these cases the incubation period before the appearance of the chancre has varied from 39 to 184 days. All the patients strongly denied any exposure to infection after having had their gonorrhoea treated with penicillin. The salient features of these seven cases are now detailed.

Reports of Cases

Case 1.—Age 33. Exposure, Dec. 6, 1944; urethral discharge, Dec. 12. Took 12 g. sulphapyridine. Seen on Jan. 10, 1945; gonococci still present in urethral smear. Blood Wassermann negative. Given 30 g. sulphathiazole, after which discharge stopped. Jan. 24: Reported with return of urethral discharge, and gonococci again present in the smears. Given 30 g. sulphadiazine. Feb. 1: No discharge; urine clear. Feb. 15: Recurrence of profuse purulent urethral discharge containing gonococci. Given penicillin in oil-beeswax suspension, 100,000 units. Feb. 16: No discharge; urine clear. Feb. 19: Routine blood tests showed both Wassermann and Kahn to be strongly positive. March 8: Course of sixty 3-hourly injections, each of 40,000 units, of penicillin started. March 9: Quantitative Wassermann titre, 36 doses. March 11: First appearance noted of indurated sore at the urinary meatus and of a scar in the coronal sulcus. The period between exposure and the development of positive blood tests was 75 days; to the appearance of a "sore," 95 days.

Case 2.—Age 23. Exposure, April 14, 1945; urethral discharge, April 19. April 21: Gonococci very numerous in urethral smear. Blood Wassermann and Kahn reaction both negative. Given 25 g. sulphathiazole, followed after an interval by 30 g. May 22: As the discharge containing gonococci still persisted he was given 4 injections of penicillin, each of 15,000 units 3-hourly (total, 60,000 units). May 23: Indurated lesion on under-surface of shaft of penis. Three successive dark-field examinations of serum were negative for *Sp. pallida*. Lesion healed satisfactorily. Blood Wassermann and Kahn negative. July 18: Blood Wassermann weak to moderately strong positive; Kahn strongly positive. Incubation period to development of "sore," 39 days; to positive blood-Kahn, 95 days.

Case 3.—Age 30. Exposure, Aug. 16, 1945; urethral discharge, Aug. 22. Seen on Aug. 23. Urethral discharge contained very numerous gonococci. Blood Wassermann and Kahn both negative. Given one dose of penicillin, 200,000 units, plus 2 minims of adrenaline. Sept. 22: Blood Wassermann negative. Oct. 1: Two small circular abrasions in coronal sulcus, not indurated and with no associated inguinal adenitis. Three successive dark-field examinations of serum were negative for *Sp. pallida*. Lesions healed by Oct. 6, and on this date blood Wassermann and Kahn both negative. Oct. 22: Routine blood Wassermann and Kahn strongly positive. Oct. 27: Slightly indurated swelling in coronal sulcus, with no erosion of skin surface. After scarification a small bead of serum was obtained, and in this a few *Sp. pallida* were demonstrated. Quantitative blood Wassermann strongly positive 10 doses; Kahn strongly positive. Incubation period, 72 days.

Case 4.—Age 35. Exposure, Oct. 30, 1945; urethral discharge, Nov. 2. Seen on Nov. 5. Gonococci very numerous in purulent urethral discharge. Blood Wassermann negative. Given one dose of penicillin, 200,000 units. Relapsed. Nov. 9: Given 4 doses of penicillin, each of 40,000 units, 3-hourly (total, 360,000 units). Jan. 3, 1946: Circular indurated lesion on shaft of penis present for one week, serum from which contained *Sp. pallida*. Blood Wassermann negative. Incubation period, 60 days.

Case 5.—Age 39. Exposure Oct. 29, 1945, urethral discharge, Oct. 31. Seen on Nov. 3: numerous gonococci were demonstrated in the purulent urethral discharge. Blood Wassermann and Kahn both negative. Given one dose of penicillin, 200,000 units. Feb. 11, 1946: Erosion on glans penis, in serum from which *Sp. pallida* demonstrated, present for four weeks. Blood Wassermann strongly positive. Incubation period 70 days.

Case 6.—Age 40. Reported on March 8, 1946. Indurated erosion in coronal sulcus present since Feb. 15, serum from which contained *Sp. pallida*. Blood Wassermann strongly positive. Last exposure on Aug. 15, 1945, in Germany. Gonorrhoea treated at that time with penicillin (no record of dosage). Strongly denied any further extramarital exposure. Wife first examined on March 9, 1946. No extramarital coitus; last marital coitus on March 2. Clinical examination negative and both blood Wassermann and Kahn negative. Kept under observation, and last seen on June 1. Blood Wassermann and Kahn tests made on nine further occasions up to that date had proved consistently negative. Incubation period, 184 days.

Case 7.—Age 25. Exposure, last week of December, 1945; urethral discharge, Jan. 1, 1946. Treated with 5 intramuscular injections of penicillin at 2-hourly intervals. Ulcer appeared at root of penis in middle of March. Seen on April 25, when he had florid secondary syphilis. Blood Wassermann strongly positive. Incubation period, 81 days (approximately).

In these seven cases the average incubation period is 82 days, being possibly heightened disproportionately by the phenomenally long period of 184 days recorded for Case 6. After excluding the doubtful No. 2, also No. 6, the average incubation period of the remaining five cases is 70 days, and, if we add to this a further 28 days, which may be

necessary for the serological tests to become positive, it is evident that well over three months may elapse before the phillix is recognized, provided, as may happen (see Case 2), the dark-field examinations of serum from the "sore" do not demonstrate *Sp. pallida*. This observation, if justified, would seem to have an important bearing on the argument that expectant mothers suffering from gonorrhoea should receive penicillin treatment in preference to penicillin in order to ward against the adverse effect on the foetus which might result from the presumed action of penicillin in delaying the recognition of a concomitant syphilis.

Commentary

In so far as the experience set out may help in the solution of the problems enunciated above, the answers provided are:

1. A two-shot technique used on an out-patient basis can provide, in male cases, a cure rate (95.8% in 190 cases) which compares favourably with the efficiency (around 95%) claimed for five- or ten-dose schemes. The two-shot cure rate achieved in 55 female cases was 90.9%.
2. The dosage of penicillin necessary to cure gonorrhoea may apparently prolong the inherently long incubation period of syphilis.
3. There is no evidence that failure of the one-injection or of the two-injection methods of treating gonorrhoea will produce a penicillin-fast strain of the gonococcus.
4. As it is only in a small proportion (2.4% in this series) of penicillin-treated cases that urethral discharge persists after the third day, the practice of giving routine irrigations is not likely to cause a significant increase of efficiency. Cases of gonorrhoea with superadded penicillin-resistant infections must be only a small minority, and, when encountered, it is reasonable to anticipate that some of them may be benefited by irrigations.

Summary and Conclusions

A one-shot or two-shot technique in the treatment of gonorrhoea is more suitable in civilian practice than the multiple-dose methods, and such limited-dose techniques can be conveniently applied to out-patients.

In 190 male and 55 female cases of gonorrhoea a two-injection scheme (2 × 200,000 units) gave cure rates of 95.8% and 90.9% respectively.

The dosage of penicillin employed to cure a gonorrhoeal infection may apparently delay the development of concomitant syphilis, and therefore penicillin-treated gonorrhoea cases should be observed for at least six months, and possibly longer.

Failure of a limited-dose technique is not likely to produce resistance to penicillin. In the penicillin treatment of gonorrhoea routine irrigation is not necessary, but may be tried if a urethral discharge persists for longer than three days.

The two-dose method advocated, using saline solutions of sodium penicillin, is simple and easily applied, the solutions used requiring no special skill in dispensing beyond the care necessary to ensure sterility and aseptis.

We are indebted to Dr. W. G. Clark, the Medical Officer of Health, for permission to publish. Our thanks are also due to the following, whose interest and help we gratefully acknowledge: Drs. Robert Lees, R. P. Jack, M. Scott-Gray, and J. Fegan; and to Sister J. Haig, Wardmaster J. Patterson, and the female and male nurses of the Edinburgh Infirmary Clinic, who carried out the injection treatment so skilfully.

The Minister of Health, in exercise of his powers under Section 2 of the Water Act, 1945, has appointed the members of the Central Advisory Water Committee. Its terms of reference are to advise the Minister of Health, or any other Minister concerned, upon matters connected with the conservation and use of water resources; on the amendment of enactments which relate to, or in any way affect, the conservation or use of water resources or the provision of water supplies; and on any question that may be referred to the Committee by the Minister in connexion with the operation, or proposed amendment, of relevant enactments. It will also consider the operation of any such enactments, and make recommendations for their extension or modification. Communications concerning the work of the Committee should be sent to the secretary, Mr. M. R. P. Gregson, at the Ministry of Health.

INDIVIDUAL RESISTANCE TO MALIGNANT DISEASE

ILLUSTRATED BY A CASE IN WHICH A METASTATIC DEPOSIT FROM A CARCINOMA OF THE BREAST OCCURRED IN THE APPENDIX AND LED TO PERFORATION AND PERITONITIS

BY

MICHAEL C. OLDFIELD, D.M., M.Ch., F.R.C.S.

Honorary Assistant Surgeon, General Infirmary at Leeds

In general we are liable to think of the human body as capable of mustering only pathetic resistance to malignant disease. It has long been recognized, however, that in certain individuals an extraordinary power of resistance can be shown. Teicher (1908), Pearce Gould (1910), Bashford, Murray, and Cramer (1907), and Schmidt (1903) proved that a varying proportion of metastatic deposits can be strangled successfully by the natural mechanisms of defence, and probably most cancer cells carried in the blood fail to establish themselves. Unfortunately, in most cases the enemy's reserves seem to be interminable, and in the end a proportion of the secondary deposits succeed in establishing themselves, and, by spreading, finally win the battle and the patient dies.

Histologically, the local defence reaction of the body to malignant disease is manifested by fibrosis and lymphocytic and eosinophil infiltration; it would appear that the body attempts to restrain tumour growth by encapsulation and strangulation. As compared with most normal tissues, malignant tumours require a correspondingly greater supply of nutrient fluid, containing especially glucose and oxygen, because of the rapidity of their growth and their wasteful methods of metabolism. Warburg (1925, 1925-7, 1930) has shown that in most malignant cells glycolysis, or fermentation of glucose to lactic acid, overshadows the normal respiratory process, in which glucose is split into carbon dioxide and water. Thus encapsulation, associated with constriction of the blood vessels supplying the tumour, may succeed in destroying malignant cells in a certain proportion of the foci. Teicher (1908) demonstrated the success of these local defence mechanisms against isolated metastatic deposits of chorion-epithelioma, one of the most actively proliferative of all tumours. He investigated the histological processes of defence in great detail and showed that metastatic deposits of tumour cells became encapsulated by an even more active proliferation of connective-tissue cells, which surrounded, constricted, starved, and finally replaced the tumour. Haemorrhage followed by coagulation, which is a characteristic feature associated with the growth of many of the most malignant nodules, also plays an important part in the destruction of tumour cells. It obstructs the supply routes to peripheral areas by pressure from within, and Teicher (1908) believes that it also stimulates the peripheral connective-tissue cells of the host to proliferate and form a fibrous encirclement. Pearce Gould (1910), Bashford, Murray, and Cramer (1907), and Schmidt (1903) have all described cases in which the local success of the defence mechanisms against isolated metastatic deposits has been proved histologically.

In 1939 Atkins made the interesting suggestion that the fibrosis occurring in chronic mastitis is part of the mechanism of defence against the onset of malignant disease. He confirmed the important work of Bloodgood (1932), who followed up a long series of cases for some years and who concluded that the incidence of breast cancer in patients suffering from a chronic mastitis is no greater than in the general population. The various types of chronic mastitis show varying degrees of epithelial and fibrous-tissue proliferation. Such epithelial activity might conceivably progress towards carcinoma if further stimulation occurred. Atkins (1939) says: "If now this fibrosis accompanies epithelial changes, which threaten cancer but rarely fulfil their threat, it is possible that the fibrous tissue may be produced in response, to that threat and may play a part in preventing it from coming to fruition. Consequently it would be just those patients who are able to develop a fibrous-tissue reaction to epithelial overgrowth—that is, those who complain of the symptoms of chronic mastitis—who would be unlikely to develop cancer."

We believe that it must be recognized that peculiar individual resistance to malignant disease occurs as well as the more generally recognized individual and organ susceptibility. Unfortunately, patients with this extraordinary resistance to malignant disease are rarely seen, and even they often succumb eventually, perhaps after a lapse of years, to the relentless attack of malignancy.

Case Report

The patient, an unmarried woman aged 40 who worked as a wool-sorter, had had a radical amputation of the left breast 3 years 8 months previously (May 29, 1933). She had been in excellent health until about one month before admission to hospital, but during the last month her appetite had been poor, and she had lost weight and energy and suffered from constipation. Pain in the lower abdomen had started suddenly at 2.30 a.m. on the day of admission (Feb. 10, 1937); in the afternoon of the same day the pain became worse and she vomited two or three times. Later in the evening the pain became even more severe, and she was brought to hospital.

On examination (Feb. 10, 1937, 9.30 p.m.) the patient was flushed and sweating, and her tongue dry and coated. Her temperature was 100.4° F. (38° C.), pulse rate 132, and respirations 36. On the left side of her chest there was a scar such as occurs after a radical amputation of the breast. There were no signs of recurrence locally or in the axillary or supraclavicular glands. The right breast appeared to be normal. The abdomen did not move freely on respiration, and there was rigidity over the lower half. The whole abdomen was tender, but the tenderness was most marked below the umbilicus and especially in the right iliac fossa. On rectal examination there was extreme tenderness in the region of the pouch of Douglas.

FIG. 1.—Transverse section of appendix and meso-appendix showing a nodule of secondary cancerous infiltration of the meso-appendix near the middle of the upper surface. ($\times 3$.)

Operation.—Under ether anaesthesia the abdomen was opened by a right paramedian incision. There was free pus in the pelvis. The appendix was perforated near its base; its distal extremity was adherent to the right side of the pelvis, and, after mobilization, the appendix was found to be stiff and extraordinarily hard. Both ovaries were enlarged, nodular, and indurated. The appendix, both ovaries, and both Fallopian tubes were removed. A rubber drainage-tube was placed in the pouch of Douglas, and the wound was closed with another (smaller) tube draining the abdominal wall.

Pathological Reports (Prof. M. J. Stewart).—(1) *Left Breast* (May, 1933):—"The tumour is a rather cellular scirrhus carcinoma which is spreading along the ducts. An outlying nodule of growth is involving some adjacent lymphoid tissue, but a separate lymph node shows no invasion." (2) *Appendix with Meso-appendix* (February, 1937):—"Wall greatly thickened. Serous surface shows a fibrinous exudate. At the distal extremity the lumen is dilated and contains frank pus. At one point there is a breach in the serous surface with numerous pale-yellow foci visible in the depths. Histological examination reveals deposits of infiltrating scirrhus carcinoma in the greatly fibrosed and thickened subserous coat." (Figs. 1 and 2.); (3) *Ovaries and Tubes* (February, 1937):—"The ovaries are enlarged and nodular. Their surface is congested and covered with adherent lymph. The Fallopian tubes show congestion of the serous coat, and their lumen is distended with clear fluid. Histological examination reveals infiltration of both ovaries and both tubes with a rather anaplastic carcinoma of scirrhus type which, from the character of the growth, most probably originated in the breast."

Progress.—The patient was severely ill for three days after the operation (February, 1937), but afterwards progress was uneventful, and the abdominal wound healed satisfactorily. An x-ray examination of the chest showed no signs of secondary deposits. On March 2 a course of deep x-ray therapy was started by Dr. J. M. Lees—200 kV 1 mm. Cu 2500 r in four weeks to five pelvic areas.

On March 10 the patient was discharged from hospital. In April 750 r to five areas was given, making a total of 3250 r in two months. On Oct. 27, 1937, the patient had gained 1 st. 2 lb. (7.25 kg.) in weight and was free from symptoms. There had been no menstrual periods since the day after the second operation. She was working, and felt "full of energy." Abdominal and rectal examination revealed no abnormality. On March 17, 1938, although the patient appeared to be in excellent general condition and had gained more

FIG. 2.—High-power view of secondary deposit in meso-appendix showing groups of cancer cells embedded in an abundant fibrous matrix. ($\times 180$.)

weight, physical examination revealed a small red indurated plaque 1/2 in. by 1/4 in. (1.27 cm. by 0.63 cm.) near the centre of the scar on the left side of the chest. As the plaque was movable over the underlying tissues it was excised, under local analgesia, with a circumscribed area of surrounding tissue.

Pathological Report (4) (March 18, 1938; Prof. M. J. Stewart).—"This portion of skin and subcutaneous tissue from the scar of the previous amputation of breast shows extensive infiltration by scirrhus carcinoma." (Fig. 3.)

In May, 1938, deep x-ray therapy was given to the left breast area by tangential fields and to the left axillary and supraclavicular regions (200 kV 1 mm. Cu 2400 r in 19 days). On May 3, 1939, the patient came to me and asked to have her right breast examined because it had "changed its shape." She was in sound general health, had gained more weight, and had no pain or other worry-

FIG. 3.—Section showing recurrence in scar of left breast. ($\times 40$.)

ing symptoms. The nipple on the right side was retracted and there was a small area of peau d'orange surrounding it for a distance of about 2 in. (5 cm.) in all directions. On palpation there was an ill-defined swelling about 4 in. (10 cm.) in diameter occupying the central portion of the breast. The swelling was adherent to the skin but movable over the deeper tissues. The glands in the right axilla were not palpable. No other abnormal physical signs were found on examination of the abdomen and pelvis, and no more nodules were palpable over the site of the left breast. Neither the left axillary nor the supraclavicular glands were enlarged. An x-ray examination of the chest revealed no evidence of secondaries.

On May 11, 1939, a radical amputation of the right breast was performed by Rodman's method at the Dewsbury and District Infirmary. The patient went home 16 days after the operation, by which time the wound had healed.

Pathological Report (5) (May 21, 1939; Prof. M. J. Stewart).—The nipple is completely retracted and slightly crusted on the surface. The substance of the breast is almost completely replaced by carcinomatous tissue, the main mass of which, in the zone beneath the nipple, measures 2½ in. (5.7 cm.) from above downwards and about 1½ in. (3.2 cm.) in depth. But the tumour tissue also spreads widely into the more remote portions of the breast and includes a nodule in the adipose tissue close to the pectoralis major muscle. There is evidence of cancerous involvement of axillary glands. Histologically the growth is a spheroidal-cell carcinoma, glandular in places and obviously very invasive. It has extended widely throughout the breast and has invaded the skin of the retracted nipple, with wide extension into the cutis vera and subcutaneous tissues of the areola, including the unstriped muscles of the nipple. Lymphatic permeation and invasion of adipose tissue are notable features. The nodule in the adipose tissue close to the pectoralis major muscle proves to be cancerously infiltrated fibrous tissue. Elsewhere in the depths of the breast there are several small cancerously invaded lymph glands and much lymphatic permeation, though without evidence of involvement of the pectoral muscle itself. The ultimate prognosis must be regarded as extremely bad."

In June, 1939, a course of deep x-ray therapy was given first to the right breast region (200 kV 1 mm. Cu 2000 r in 20 days), and further irradiation was given to the pelvis (200 kV 1 mm. Cu 2000 r in two weeks) and to the left breast (200 kV 1 mm. Cu 2000 r in two weeks). On Oct. 23, 1939, the patient was going out to work again and felt "perfectly well."

Comment

Whilst abroad I received a letter from her sister-in-law telling me that after a short illness my patient had died in July, 1941. She had insisted upon going to work to within a fortnight of her death.

The patient lived just over eight years from the time of removal of the left breast for a frankly malignant type of cancer. She showed remarkable resistance to the disease even after secondaries had appeared. It is also interesting to note that a second cancer, which was considered to be another primary, started in the opposite breast two years after bilateral oophorectomy had been performed.

Metastatic carcinoma from the breast as a cause of perforation of the appendix and general peritonitis must be extremely rare. No record of a similar case has been found in the literature.

Summary

Some of the natural defence mechanisms against malignant disease are discussed. Certain individuals seem to have exceptional powers of resistance to cancer.

A case is described in which a carcinoma of the left breast was removed before the menopause, and a secondary deposit involving the appendix led to perforation and general peritonitis 3 years and 8 months later. The appendix and both ovaries were removed. A year later a recurrence in the original breast scar was excised. The following year a carcinoma, thought to be a second primary, appeared in the right breast, and a radical amputation was performed. The patient died just over eight years after the original operation upon the left breast.

I wish to express my grateful thanks to Prof. M. J. Stewart for his kind help and advice.

BILIARY PERITONITIS WITHOUT DEMONSTRABLE PERFORATION

BY

D. P. BURKITT, M.B., B.Ch.Dub., F.R.C.S.Ed.

Major, R.A.M.C.; Surgical Specialist

Biliary peritonitis results from the escape of bile into the peritoneal cavity, which excites a marked peritoneal reaction, whether the liberated bile be infected or sterile. Three main varieties of the condition have been described according to the underlying pathology. Injuries to the biliary tract and perforations of the gall-bladder in acute cholecystitis account for the large majority of cases. A number of cases have been recorded in which no perforation could be found. This so-called "perforationless biliary peritonitis" is a rare condition which was first described in 1905 by Maurice Richardson. No general interest in this pathological entity was evoked, however, until Clairmont and von Haberer published a paper on the subject in 1910.

Symptomatology and Pathology

The clinical picture has shown wide variations, and cases have been described simulating perforation of a peptic ulcer (Illingworth and Dick, 1941), with a less sudden development resembling peritonitis resulting from perforation of the appendix (Buchanan, 1918), or of still more gradual nature, with increasing abdominal distension, vomiting, and a rising pulse rate (Rolleston, 1938).

In the cases with a relatively acute onset, which constitute by far the greatest number, remission of symptoms after the first acute attack has been the one almost constant feature (Cope, 1925-6). This can be explained by the fact that sterile human bile, differing from the bile of experimental animals in its small content of the toxic salt sodium taurocholate, is only slightly irritant after the initial concentrated effusion has been diluted by peritoneal exudate. Further, cases are on record where over 30 pints (17 litres) of bile, presumably diluted by ascitic fluid, have been aspirated from the peritoneal cavity over a period of six weeks.

The pathology would appear to be almost as variable as the symptomatology. While a grossly discoloured and almost necrotic common bile duct associated with a tense red gall-bladder has been described (Buchanan, 1918), the biliary system has also been found apparently intact (Rolleston, 1938). Thirteen out of sixteen cases reviewed by Buchanan (1918) showed inflammatory or carcinomatous lesions of the biliary tract or stones. Of the remaining three, one gave a history of trauma and one was thought to be due to typhoid ulceration.

Pohlmann (1939) describes a case with acute inflammation superimposed upon a chronic cholecystitis. Although the cystic duct was blocked and the tense gall-bladder was covered with fibrinous exudate, no perforation could be found to account for the biliary effusion.

McLaughlin (1942) reports eight cases of biliary peritonitis, but all except one of these fall into a different category, since they were a sequel to cholecystectomy. He suggests that in many such cases the leakage of bile is accounted for by accessory hepatic ducts entering the gall-bladder direct from the liver. Others are almost certainly due to duct perforation resulting from increased pressure in the biliary tree caused by overlooked stones in the common duct. The only case that was not post-operative showed at necropsy a gangrenous gall-bladder with stones in both the gall-bladder and the common duct. No perforation could be demonstrated. Four of the post-operative cases were fatal, and in three on which necropsy was performed stones were found in the common duct. Perforations of the cystic duct stump were found in two.

Smith (1926) reviewed 12 fatal cases, all with rupture of intra-hepatic ducts and with a history of calculus, cholecystitis, and intermittent symptoms of common-duct obstruction.

Retroperitoneal extravasation of bile was a characteristic feature in two cases described by Cope (1925-6). In one of these the overlying peritoneum appeared to "weep" bile, but no perforation could be found.

Nurses and midwives of the Commonwealth and Empire have already raised more than £17,000 as a memorial to their colleagues who fell in the war of 1939-45, and the Queen has shown her appreciation of their effort by consenting to become the Patron of the fund to which they are contributing—the British Empire Nurses War Memorial Fund—and the Princess Royal has consented to become Vice-Patron. The address of the fund is Dorset House, Stamford Street, London, S.E.1.

It has been suggested that post-peritoneal rupture or perforation of the common or hepatic ducts results from trauma or ulceration and leads to biliary effusion into the retroperitoneal tissues with subsequent rupture into the peritoneal cavity at a point more or less removed from the site of the perforated bile passage (Buchanan, 1918). This would seem a possible explanation of the two cases with retroperitoneal effusion referred to above.

Glands of Luschka which have penetrated abnormally deeply through the muscular coat of the gall-bladder have been cited as a possible path by which bile may escape, but in view of the very strong safeguard the overlying peritoneum presents against intraperitoneal extravasation this would appear improbable. German authors (Kaufmann, 1929) have blamed percolation and filtration of bile through the wall of the gall-bladder either as a form of diapedesis or as a result of digestion of the wall by pancreatic trypsin.

Ruptures of the intrahepatic bile canal have been found at biopsy, and have all been associated with obstruction to the common duct by stone or carcinoma (Buchanan, 1918). Perforations of a subserous bile duct on the liver surface have also been described.

McLaughlin (1942) remarks that in the majority of recorded cases a small perforation could be demonstrated, though often only by serial sections at the site. Because of their small size these would leak only when the intraperitoneal pressure was increased, closing spontaneously when the pressure was relieved. The natural tendency to spontaneous closure which these organs show is well known, and is attributed in part to the low pressure of bile excretion and the readiness with which adhesions to neighbouring viscera form.

Burckhardt (1923) also believes that there must always be a perforation, either not found or already healed. If this theory be correct at least a temporary obstruction to one of the bile passages must be assumed to promote the escape of considerable quantities of bile through a small opening.

Case Report

A tall well-built man aged 26 was admitted to hospital on May 16, 1945. Five days previously, when walking down the street, he felt a sudden pain in the upper abdomen which lasted probably less than a minute, but caused him to stand still during that time. Two days later he noticed that his urine was dark in colour and he began to suffer from nausea, lack of appetite, and lethargy.

On clinical examination nothing abnormal was detected beyond a yellow tinge in the sclerotics and slight tenderness in the right hypochondrium. Bile pigments were demonstrated in the urine. The leucocyte count was low (5,600), but the differential count showed no abnormality. On the day after admission jaundice was discernible. The van den Bergh reaction was immediate direct. The jaundice continued to deepen, and the patient vomited frequently. He was afebrile throughout and at no time was a raised pulse rate recorded. The patient noticed a change in the colour of his stools, which struck him as being abnormally light in colour, but this information was not obtained till later.

Twelve days after admission, in the early morning, he developed severe pain of very sudden onset, which was first felt between his shoulders posteriorly. He was returning from the lavatory when the pain began, and he found it difficult to straighten his back. A few moments later he felt pain in his abdomen. On examination two hours later he showed the clinical picture of acute general peritonitis, with abolition of abdominal respiration and generalized board-like rigidity. Tenderness was maximal in the right hypochondrium, and the flanks were dull on percussion. Nothing abnormal was detected in the chest.

A diagnosis of acute general peritonitis, possibly due to rupture of the gall-bladder or bile ducts, was made, and it was decided to perform laparotomy immediately. A drip blood transfusion was begun before starting the operation.

Operation.—Pentothal was given through the intravenous tube, supplemented by gas and oxygen. The abdomen was explored through a right upper paramedian incision. The peritoneal cavity was filled with a golden-brown fluid resembling bile, and amounting to about two pints (1.14 litres). In the absence of a sucker this was mopped out with towels. The upper abdominal organs were carefully and systematically examined. The liver appeared slightly congested but showed no gross pathology. The gall-bladder was thickened, suggestive of some chronic inflammation, but the peritoneal covering was healthy and intact, and no stones were palpable. The contained bile was not under tension and emptied easily on pressure. No perforation or other lesion could be found in the

cystic duct, the common bile duct, or the common hepatic duct. Both stomach and duodenum were normal. The pancreas was palpated and visually inspected through the lesser sac, and no lesion was found. The spleen was not enlarged. Inflammation of the bowel surface and other signs of acute infective peritonitis were entirely absent.

Some of the peritoneal fluid was collected in a sterile test-tube and was observed to coagulate almost immediately. A pelvic drain was inserted through a suprapubic stab wound. The peritoneum and rectus sheath were approximated with No. 2 twenty-day catgut. Cotton thread was used for ligatures and silkworm-gut for tension sutures and skin.

The drip blood transfusion was continued until two pints (1.14 l.) was given, and this was followed by intravenous saline to ensure adequate fluid and glucose intake until the patient was able to swallow fluids without vomiting.

After-history.—On the day after operation the intravenous drip was discontinued. There was profuse discharge of bile-stained fluid from the suprapubic tube. The peritoneal fluid was reported on as containing bile pigments. (It was sterile after seven days' culture.) The patient's general condition was poor, and his pulse varied from 110 to 130, and his temperature from 101 to 103° F. (38.3 to 39.4° C.). Jaundice was unchanged and bile pigments were still present in the urine. A bad taste in the mouth was a prominent symptom. The next day, much of the oral intake being vomited, an intravenous drip was restarted. The vomit was deeply bile-stained and was strongly positive to Hay's test. The leucocyte count had risen to 12,400. On the fourth day jaundice was noticeably disappearing, and his condition was much improved. The urine was bile-free. The suprapubic tube was removed. The following day the drip was considered no longer necessary. On the seventh day the sutures, which were cutting through the skin, were removed, and the skin edges appeared firmly united. Shortly after the patient "cleared his throat" and the wound fell apart and bowel protruded. Under pentothal anaesthesia the prolapsed bowel was replaced and the wound edges approximated with through-and-through sutures of stout silk. At this second operation there was still a small quantity of bile-stained peritoneal effusion. There was no sign of the catgut used to close the wound a week previously, nor was there any evidence of inflammation of the bowel wall. This complication resulted in a deterioration in the general condition, and intravenous glucose-saline was restarted, raising the systolic blood pressure from 80 to 120 mm. in the three hours following operation.

With the exception of a collapse of the base of the right lung the patient made steady progress, though there was considerable inflammatory reaction round the wound. A good formed motion of normal colour was passed on the eleventh day after the first operation. Three days later jaundice had almost disappeared.

Bile staining persisted in the discharge from the abdominal wound, and did not entirely disappear until four weeks after the abdominal crisis. Two weeks later a cholecystogram was done and showed deficient filling of the gall-bladder with poor concentration and delay in emptying. No calculi were seen.

Comments

The peritoneal effusion in this case was proved to be bile, from which no organisms could be cultured. The maximum intensity of jaundice coincided approximately with the abdominal crisis, after which both the jaundice and the bile content of the urine began to diminish. The pale colour of his stools attracted the patient's attention for several days before operation, but it was not possible to ascertain whether they were entirely free of bile pigment. The presence of bile in the post-operative vomit excludes the possibility of common-duct obstruction at this stage. A diagnosis of either infective hepatitis or obstructive jaundice is compatible with the history and findings in this case, at least until the advent of an abdominal crisis. Epigastric pain is apparently a not uncommon symptom in the former condition, which was the accepted pre-operative diagnosis. If this was a case of infective hepatitis, however, it is extremely difficult to postulate how the biliary effusion may have occurred. Obstructive jaundice is therefore considered a more likely explanation, being consistent with the symptomatology while at the same time offering a possible explanation of the biliary effusion, and one which is in keeping with the findings of at least a considerable proportion of the reported cases.

It is suggested that at the first attack of pain, before the appearance of jaundice, a small stone passed down from the gall-bladder, which from operative findings and a cholecystogram is known to be pathological, and lodged at or near the ampulla of Vater. This would result in jaundice and increased obstruction in the biliary system. A small perforation possibly occurred in the lower part of the common bile duct, which does

not lend itself to visual inspection. This may have been temporarily plugged with the stone, permitting the escape of bile as soon as it left its site of impaction.

The effusion would in this case be first of all retroperitoneal, accounting for the fact that the initial pain during the abdominal crisis was clearly located to the back. The intra-peritoneal effusion would follow a secondary perforation through the peritoneum, as suggested by Buchanan (1918). It will be remembered that Cope (1925-6) described the peritoneum as "appearing to weep" bile.

The obstruction to the biliary system was possibly not released until after the initial escape of bile. After the relief of tension in the common duct the perforation would tend to close spontaneously.

EPIDEMIC PLEURITIC PAIN

A REVIEW OF 17 CASES IN A MILITARY CAMP,
INDIA COMMAND

BY

J. ROCHE, M.B., B.Ch.

Capt., R.A.M.C.

AND

F. G. SMIDY, M.B., Cb.B.

Capt., R.A.M.C.

During the period December, 1945, to January, 1946, a series of cases presenting themselves as pleurisy occurred in an Indian military camp for British personnel. The clinical picture led us to believe that the usual textbook accounts of dry pleurisy, which emphasize the tuberculous aspect, are unbalanced.

Symptomatology

The cases occurred in young troops arriving in India from England, and were seen in the space of six weeks. Coryza and pharyngitis were common owing to inhalation of dust and to change in climate. Pain in the chest was present in all cases with the exception of two. The men were not ill, and when asked if they would have continued at work in civilian life the majority answered "Yes." More than half reported sick with both pain and upper respiratory tract infection, while others gave a history of the latter during the previous three weeks. The pain was pleuritic in type, mostly localized to the lower thoracic region in the axillary line, and in two cases was felt in the second left intercostal space. It lasted from two to twenty-one days, and the majority of patients had a cough with slight sputum. In some cases there was local tenderness on pressure over the painful area. A pleural rub was heard in three cases, and six showed signs of a parenchymal lesion in the lung. These signs were fleeting, and for the most part consisted of localized crepitations at the site of the pain. They were heard in late inspiration and early expiration, and in one case disappeared after the first few deep breaths. The crepitations persisted after coughing.

It must be emphasized that the physical signs in the chest were transitory. One case presented with pain in the chest and had no physical signs until the sixth day, when crepitations were heard over the site of the pain. Another case had symptoms of pleuritic pain without physical signs over a period of fourteen days; physical signs suggesting a pleural effusion then occurred, but skiagrams showed a parenchymatous lesion of the right lobe—a pneumonitis.

Only four cases were pyrexial, the temperatures ranging from 100.6° F. (38.1° C.) to 103.8° F. (39.9° C.). Of cases transferred to hospital one developed a lung abscess, while another, de-

scribed above, showed radiological evidence of a pneumonitis. On being screened six others showed no radiological lesion whatsoever. Three patients had the blood sedimentation rate estimated: one was normal, one was 17 mm. (after an hour), and a third showed the series 39-20-9 mm. (after an hour) over a period of three weeks after admission. In no case was the leucocyte count abnormal.

A Typical Case

On Jan. 10, 1946, a youth aged 19 had a brief illness consisting of headache, sore throat, and rhinitis, with a temperature of 103° F. (39.4° C.). Next day there was no pyrexia, and the symptoms resolved. On the fourth day the temperature rose to 102° F. (38.9° C.) without any symptoms other than sweating. Blood slides were negative for malaria parasites. There was no rash or any further pyrexia. This was not a case of dengue fever, but an upper respiratory tract infection.

On Jan. 21 he developed pleuritic pain in the left second intercostal space, with a temperature of 100.6° F. (38.1° C.). There was a slight cough, but no sputum. At the site of the pain crepitations were heard for the first few breaths on deep inspiration. On Jan. 22 the pleuritic pain was less severe, and persistent crepitations were heard in the same position. On Jan. 23 the patient said the pain was felt only in the early morning. Temperature, 99.4° F. (37.4° C.). No signs were present in the chest. There was no further pyrexia and no further pain. The patient is quite well to-day.

Discussion

Access to literature was limited owing to difficulties of travel, and on account of Service conditions observations on the diseases are largely clinical. The cases sent to hospital were followed up there, but once the benign nature of the condition was realized they were treated in bed in the camp hospital for a few days.

The differential diagnosis lies between: (1) a pleurisy of tuberculous origin; (2) epidemic myalgia (Bornholm disease); (3) atypical virus pneumonia; (4) a benign condition such as that described by Williamson (1924) under the name of "epidemic pleurisy."

There are many reasons for not considering the condition a tuberculous process. In no case was there a suggestive personal or family history. With the exception of two, both now well, the condition was benign and recovery rapid; most of these patients were off duty for less than two weeks, and none developed a pleural effusion. Another point against tuberculosis is that a number of cases occurred in a short time among healthy troops—i.e., the condition was epidemic.

Epidemic myalgia, as first described by Daac in 1874, shows points of similarity, but there are differentiating features. Our chief reference is the Cincinnati outbreak of eleven cases. Here a syndrome was described in which the pain in the chest was severe and occurred in paroxysms, sometimes numbering five in all, with periods of quiescence during which the patient was comfortable. The quiescent periods lasted 24 to 30 hours. In our cases the pain was not usually intense, and was of definite pleuritic type; there were no intermissions. Fever of low grade is common to both syndromes. In the Cincinnati outbreak there were no physical signs, and this is our criterion for differentiation; physical signs were present in the majority of our cases, and were fleeting enough to make us think that we should have heard them in more if we had had the opportunity for further observation. We must agree that our cases seem to have taken an epidemic form, since they all occurred in a space of six weeks; and there were other cases in neighbouring camps, all showing the same benign process, migrating to the same hospital. Also, the end of the epidemic was coincident with a considerable fall in the numbers passing through the camp. Local tenderness may occur in both pleurisy and epidemic myalgia. Atypical virus pneumonia is ruled out by the absence of pyrexia in most cases and the fact that the patients were not ill; those in hospital showed no radiological evidence of the affection.

In 1924 Williamson described a condition having an onset resembling "subacute influenza," with pyrexia of short duration followed closely by pain of pleuritic type. In seven of his thirteen cases he detected a pleural rub, but no case developed

an effusion. Pickles, of Aysgarth, also in 1924, described a series of epidemics under the same name; pleural rubs were heard and there was pyrexia, with signs of upper respiratory tract infection. We believe that our cases were examples of the above condition; but data other than clinical evidence are lacking and we have failed to follow up our cases over a long period. Two have been followed, however, for four months; both are healthy men—Al and capable of carrying out any duties. The nature of the condition appears to be that of a dry pleurisy sharply localized, with a small underlying parenchymal lesion of the lung. It would also seem that it is secondary to an upper respiratory tract infection, which descends either in the air passages or in the lymphatics. In many cases of upper respiratory tract infection which we saw there was thick mucus in the nasopharynx; and in those cases of pleurisy occurring at the same time as the upper respiratory tract infection it is reasonable to assume that the infection spread down the air passages. In those in which the nasopharyngitis had apparently occurred some time previously the infection had probably persisted and then spread downwards; for we have found that mild infections such as coryza and pharyngitis are persistent in India. The lesion in the lung is superficial enough to give rise to physical signs, but does not penetrate deeply enough to be opaque to x rays.

A CASE OF HUMAN RABIES IN SIERRA LEONE

BY

E. JENNER WRIGHT, M.B.E., M.R.C.S., D.T.M.

Specialist Physician

AND

MINNIE GOSDEN, M.B., B.S., D.T.M.&H.

Senior Pathologist

Colonial Medical Service, Sierra Leone

This is the first case of human rabies reported in Sierra Leone which has been confirmed by animal inoculation, and is the only case notified during the last eleven years. It is of interest to note that this case was consequent on a cat-bite, and in view of the endemicity of canine rabies in this territory the paucity of reports of human rabies is surprising.

Case History

The patient, a 7-year-old African boy, was brought to the outpatient department of the Connaught Hospital, Freetown, at noon on Jan. 23, 1946, and was admitted to the wards in a restless state. Early on the morning of Jan. 10 a strange cat appeared at the door of the patient's house and was stoned by some of the young inmates, whereupon it hid near a fence in an abandoned cupboard. The patient, the last to come down that morning, went outside to urinate as was his custom and chose a spot near the abandoned cupboard. Whilst he was urinating the cat flew at him and bit him on the upper lip. Another child, seeing his plight, hit the cat, and it returned to hide in the same place. The cat was then stoned to death in its hiding-place, but unfortunately its body was not produced for post-mortem examination.

The bitten child was taken to a hospital near by, where the lip wound was stitched and dressed, after which he was referred to the Connaught Hospital, where the wound was further treated and the first dose of antirabic vaccine given, with instructions that he be brought in the morning to continue the course of prophylactic injections; but this was not done. Four days later (Jan. 14) the bite was nearly well. The child started going to school and remained in apparent good health until the 22nd, on which day he vomited early in the morning. His mother gave him a dose of "worm oil," which purged him, but he was feverish until evening, refusing to eat rice but taking pap. He played that evening and went to bed much improved; but at midnight his skin was hot again, and he was panting, so his mother woke him up; but he said nothing was wrong and slept again. The panting recurred twice or thrice before daybreak, when he complained of pain in the throat and later started retching. By 10 a.m. that day he was so ill that he was brought back to hospital.

Clinical Findings.—On admission at 1 p.m. on Jan. 23 he was seen to be having spasmodic attacks of fear and to be making

jerking movements of his arms. The tongue was furred and moist; T. 101° F. (38.3° C.), P. 72, R. 28. There were no appreciable findings in the various systems, and he was able to swallow. A provisional diagnosis of rabies was made, and he was isolated. In view of the history of cat-bite, with only tentative diagnosis of rabies, an intensive course of antirabic vaccine was started; meanwhile a more definite diagnosis was being made. Sedative treatment was also given.

Progress Notes.—At 3.15 p.m. on Jan. 23, the day of admission, the child behaved normally and then had a sudden spasm with generalized twitching, which started with difficult breathing. By 6.10 p.m. the sedative mixture had had no effect, and he was now unable to take anything by mouth, so an intramuscular injection of 4 ml. of paraldehyde was given. At 6.30 p.m. the child was sitting up and showed great fear when offered water; but he was persuaded to take some and immediately jumped about and held his stomach as if in pain. He retched continuously for five minutes and spat a great deal. By 9.15 p.m. he was fairly quiet.

The following day, at 9.30 a.m., he was sitting up. He refused even to look at water, and when it was offered hid his face by turning to the wall. He agreed to take some pap, but eventually refused to touch it. A lumbar puncture was done under general anaesthesia. The cerebrospinal fluid came away clear and not under pressure. At 1.30 p.m. he was sitting up. On being spoken to he held out his right arm and made movements in a slow deliberate manner, protruded a furred tongue on request, and then made a few spasmodic respirations. At 4 p.m. he was restless, made very jerky movements, which recurred at intervals, and was expectorating coffee-brown sputum. Paraldehyde 5 ml. was injected. At 6.30 p.m. the symptoms were restlessness, embarrassment of respiration, and sniffing with markedly dilating nostrils; he was kicking his legs about as if trying to interwine them. He seemed to be conscious of what was happening. At 7.30 p.m. he was still restless, and there was only a very slight sedative effect from the paraldehyde so far given. At 9.30 p.m. an intramuscular injection of 6 ml. of paraldehyde was given, and at 10 p.m. death occurred.

Post-mortem Findings.—Necropsy was performed on Jan. 25, twelve hours after death. The body was that of a rather poorly nourished African boy of apparently 7 years of age. Rigor mortis was present. There was a recent healed scar on the right side of the mouth, and old scars on the shins. The hands were clenched, and the finger-nails intensely cyanosed; there was less marked cyanosis of the toe-nails. **Thorax:** The heart showed scattered petechial haemorrhages on the visceral pericardium, especially along the auriculo-ventricular groove. The larynx and trachea were normal in appearance; the lungs were rather dry and pale, and filled the chest; there were scattered small subendothelial haemorrhages on the visceral pleura. **Abdomen:** The stomach was empty; the intestines showed no abnormality, and the liver, spleen, and kidneys were markedly congested. **Head:** On opening the skull the dura was bulging; the brain was rather soft; the grey matter was a generalized dark pink; there were small haemorrhages in the floor of the fourth ventricle.

Histological Examinations.—Sections of the brain showed well-marked cuffing of the vessels, with patchy degeneration of the neurons and cellular infiltration among the degenerated cells in the medulla, pons, and basal motor ganglia. The rest of the brain was not affected. No Negri bodies were found. The liver revealed cellular infiltration and some fibrosis around the main bile ducts, artery, and vein. There was black pigment in the Kupffer cells. The kidneys showed cloudy swelling of the tubular epithelium.

Animal Inoculation.—Subdurally, 0.2 ml. of a glycerinated extract of the brain of the child was inoculated into a rabbit. The animal died on the fifteenth day after inoculation. Histological examination of the brain showed a diffuse encephalitis, with marked cuffing of the vessels. Negri bodies were present.

Laboratory Investigations (Jan. 24).—**Urine:** Reaction acid; a thick cloud of albumin; no sugar; acetone present. **Blood:** Culture sterile; R.B.C., 5.3 million per c.mm.; white cells, 18,600 per c.mm.; Hb, 13.5 g. per 100 ml.; M.C.H., 26 γ ; M.C.V., 81 c μ . Differential count: neutrophils, 51%; eosinophils, 2%; small lymphocytes, 30%; large lymphocytes, 9%; large hyalines, 8%. C.S.F.: Clear fluid. No clot on standing. Cells, 44 per c.mm. (lymphocytes). Protein, 30 mg. per 100 ml.; chlorides, 770 mg. per 100 ml.

We are indebted to the Honorary Director of Medical Services, Sierra Leone, for permission to publish this paper, and to Mr. W. Quin, Surgical Specialist, for seeing the case and performing a lumbar tap under general anaesthesia.

Revised recommendations of the Nurses' Salaries Committee for the salaries of, among others, matrons, head nurses, qualified sister tutors, night staff, student and pupil assistant nurses, and male and public health nurses are contained in "Nurses S.C. Notes No. 12," which has just been issued (H.M. Stationery Office; 4d. net). The new scales will have effect from Jan. 1, 1946.

AMENORRHOEA AT STANLEY CAMP, HONG KONG, DURING INTERNMENT

BY

ANNIE SYDENHAM, M.R.C.S., L.R.C.P.

Medical Officer in charge of Obstetrics and Gynaecology, Alice Memorial and Affiliated Hospitals, Hong Kong

Amenorrhoea is well known to occur as the result of emotional shock, change of environment, and metabolic disturbances, either nutritional or endocrine. A situation in which all these factors may have been operative upon a large number of women, and which gave rise to amenorrhoea in over half of them, is worthy of record.

A month after the fall of Hong Kong on Dec. 25, 1941, British civilian subjects were interned in Stanley Camp. Periodical medical surveys were conducted in order to ascertain the state of health and nutrition of internees. The following is a summary of the menstrual histories which were obtained at the time of the first medical survey of 655 women made in July/August, 1942:

Group 1: Postmenopause ..	205
" 2: Amenorrhoea of pregnancy and lactation ..	14
" 3: Regular menstruation ..	152
" 4: "Irregular" menstruation, with increased frequency of menstrual periods, and menorrhagia ..	20
" 5: Amenorrhoea:	
(a) Delay up to 60 days ..	30
(b) Delay for over 3 months ..	234

Omitting groups 1 and 2, a survey of the remaining 436 women between the ages of 15 and 45 years, who would in normal circumstances be menstruating regularly, reveals that only 34.86% had regular menstruation; 4.59% were irregular, with menorrhagia, and 60.55% had amenorrhoea (53.67% with amenorrhoea for more than three months). Absence of menstruation was a convenience, especially in the early months of internment, and treatment was given only in cases presenting symptoms of discomfort.

Symptoms and Treatment

(a) The most constant symptom was excessive gain in weight in the form of flabby unhealthy fat. This was in marked contrast to the majority of women in camp, who lost weight. The patients suffering from excessive gain in weight with amenorrhoea were usually young women, and, although the chief reason for this condition was probably the unaccustomed excessive rice diet, it was considered that thyroid deficiency might also be a factor.

(b) In other patients the chief symptoms were nervousness and irritability or depression at the time the period would normally be due, sometimes associated with distension and discomfort in the abdomen. For these it was considered that additional ovarian stimulation might be of use.

Our supplies of drugs were very limited. We had small quantities of thyroid extract and of menformon injections. Group (a) were treated with the former and group (b) with the latter. Some patients received benefit from the treatment, but, owing to scarcity of drugs and of facilities for investigation, the results were inconclusive.

Length of Period of Amenorrhoea

Of the 234 women with amenorrhoea for more than three months, 81 had restarted menstruating within six months, and all except six had menstruated within 18 months (i.e., by May, 1943), although a number stopped again in the early months of 1944. Six women were known to have had amenorrhoea through the whole period of internment—i.e., 45 months. I have been able to get into touch with two of them since arriving in this country. In one patient menstruation restarted after 48 months without treatment, following a stay on a farm with good fresh food. The second patient was under treatment for three months, and menstruation was re-established after 51 months' amenorrhoea. (This patient had lost her husband in the fighting in Hong Kong on Dec. 25, 1941.)

It is interesting to note that a number of women between the ages of 45 and 50 ceased menstruating in December, 1941.

and had amenorrhoea throughout the internment. These cases were considered to be menopausal and are not included in the "amenorrhoea" figures, although they were surprisingly free from any menopausal symptoms other than amenorrhoea.

Possible Causes for Cessation of Menstruation

The emotional shock of war and internment, with the change of environment and occupation, was no doubt the initial cause of the amenorrhoea. It is difficult, however, to attribute to this factor alone so long a period of amenorrhoea as a year or more in many cases, although the food factor could not have come into the picture until later; for in most instances amenorrhoea dated from December, 1941, before the effects of undernourishment on general metabolism could have been manifest.

Undernourishment, especially deficiency of proteins (either "first-class" or other proteins); also possibly vitamin deficiency. The protein content of the rations never reached the normal minimum requirement, but it came nearest to this after a Red Cross shipment reached us in November, 1942, containing a large supply of tinned meat. Apart from this welcome addition to our protein, which lasted for about six months, we were about 30g. per day below the minimum requirement of 75 g. per day, the chief shortage being in animal protein. From December, 1942, to May, 1943, even the most resistant cases of amenorrhoea, with the exception of six, cleared up. Some meat or fish was included in the Japanese rations for the remainder of 1943, but in January, 1944, meat stopped, and did not reappear in the menu until the last eight weeks of our internment. For a few months in 1945 even the fish supply disappeared entirely, and our only proteins were obtained from soya beans and root vegetables. The average value of the rations amounted to about 1,600 calories daily, of which 1,200 were derived from rice. The second "wave" of amenorrhoea started in the early months of 1944, after the meat ration ceased. It may be argued that our poorer Chinese patients who came to gynaecological clinics before the war were not suffering from amenorrhoea, although they were living on a diet similar to ours, but the change in our diet had been sudden both in quality and in quantity.

Summary

In Stanley Internment Camp, Hong Kong, from January, 1942, to September, 1945, 53.67% of the women between the ages of 15 and 45 suffered from amenorrhoea of more than three months' duration.

A few women presenting symptoms of discomfort were treated with the available drugs—namely, thyroid extract and menformon injections.

Within six months 81 women had started menstruating again, and within 18 months menstruation was re-established in all except six cases, which persisted throughout the period of internment.

Possible causes of amenorrhoea are discussed under the headings of (a) emotional shock, and (b) undernourishment with special reference to protein deficiency.

Medical Memoranda

Delayed Appearance of a Syphilitic Chancre after Penicillin

Because of the curative effect of penicillin on syphilis, it is reasonable to suppose that a small dose may delay the onset of the appearance of a primary syphilitic chancre. It has been shown that the amount of penicillin usually given for cases of gonococcal urethritis is sufficient to destroy surface spirochaetes and lead to the partial or complete healing of a syphilitic chancre.

Walker and Barton (1945), in a review of cases in which a papule had already been noticed, only stress the temporary masking of the primary state, and maintain that all patients should be observed for at least twelve weeks. Cronin (1945) describes ten cases of gonorrhoea treated with penicillin in which syphilis subsequently developed. In his cases the average time interval from penicillin treatment to the appearance of the chancre was 38.9 days, and from the probable date of exposure 47.2 days. He suggests that the incubation period may have been delayed by days rather than weeks, and therefore that surveillance of

iorrhoea

to exclude syphilis does not require to be extended beyond the customary three months.

The incubation period which elapses between the implantation of the spirochaete and the appearance of a visible lesion is generally under six weeks. An incubation period longer than two months, though described, should be regarded with suspicion. Until recently it has generally been the custom in this country to put cases of gonorrhoea on surveillance for three months. That this may not be long enough is suggested in the case described.

CASE REPORT

A male patient aged 29, who denied previous venereal infection, had reported elsewhere on Jan. 3, 1946, with a gonococcal urethritis. He admitted exposing himself to infection three days previously. Penicillin, 200,000 units given in 3-hourly doses all tests were quickly cured his gonorrhoea. While on surveillance all tests were negative until he reported to this hospital on April 10. He complained that he had had a sore on his penis for seven days, which was not healing. On examination he was found to have a typical indurated syphilitic sore on the shaft of the penis, with marked inguinal adenitis. Dark-ground examination of material from this sore showed large numbers of treponemata. A Wassermann test on a sample of blood taken at the same time was negative. This finding fits in with the story of the patient that the sore had been present only for seven days. On questioning he stated that he had run no further risk since Jan. 1, 1946, and was able at the same time to name the prostitute with whom he had taken the risk. I believe his story to be true.

On tracing the record card of the prostitute it was found that she had been treated for gonorrhoea in May, 1945; in the following September she had had salpingitis, but had defaulted since October. She reported again to the clinic on Feb. 25, 1946, with condylomata around the posterior fourchette, in specimens from which *Treponema pallidum* was easily recognized on dark-ground examination. Her blood Wassermann was strongly positive. Gonococci were not found in smear or culture from either urethra or cervix. It can, however, be presumed that she was doubly infectious on Jan. 1, 1946, and therefore the almost certain source of the infection in our male patient.

The case is interesting in suggesting that, as had already been tentatively postulated, the onset of primary syphilis may be considerably delayed after treatment with penicillin. It is to be expected that further cases similar to this will be described.

Cronin's article is useful in showing that a long delaying action is probably not at all common; however, if some cases can occur, three months is too short a period for surveillance of cases of gonorrhoea, since infection with syphilis may pass undetected. This is particularly important in women, when the chancre may not be obvious—e.g., when it is on the cervix.

My thanks are due to Dr. G. L. M. McElligott, Director of the Department, for permission to publish this case.

A. W. FRANKLAND, B.M., B.Ch.,
Assistant Medical Officer, Venereal Diseases Department.

St. Mary's Hospital, London.

Silent Perforation of the Gut Wall

The recent report (*Journal*, March 2, p. 315) of a case of a foreign body piercing the gut wall and causing an "acute women" has prompted me to place on record the following which show that, apparently, silent perforation of the wall can occur.

The patient, an intelligent woman of 33, was admitted to this hospital with a typical history, signs, and symptoms of acute appendicitis. An early acutely inflamed appendix was removed, and when arranging the greater omentum to protect the operation site a hard mass was felt in the omentum. On inspection this proved to be a rubber ring embedded in the omentum about 1 in. (2.5 cm.) from the transverse colon. There was some discoloration of the surrounding fat but no evidence of ulceration through the bowel. Resection of a small wedge of omentum containing the ring was performed and the abdomen closed. The patient made an uneventful recovery.

Careful questioning of the patient afterwards failed to bring to light any explanation of the route which the ring must have followed. She had never had any previous stomach trouble such as one would expect when this foreign body was ulcerating through the gut wall. The only explanation which occurs to me is that the ring, presumably ingested, ulcerated through the greater curvature of the stomach between the anterior two layers of the greater omentum, and so was never free in the peritoneal cavity. In this way the absence of symptoms may be explained.

I wish to thank Mr. L. E. C. Norbury, under whose care the patient was admitted, for advice and encouragement in the reporting of this case.

W. HOUSTON, M.Ch., F.R.C.S.,
Surgical Registrar.

Reviews

THE COMPOSITION OF FOODS

The Chemical Composition of Foods. By R. A. McCance and E. M. Widdowson. Second edition. (Pp. 156, 6s.) M.R.C. Special Report Series No. 235. London: H.M.S.O. 1946.

Six years ago Prof. McCance and Miss Widdowson published their *Chemical Composition of Foods*, a compilation giving the most important organic and mineral constituents of the more common foodstuffs. The steady demand for this book over the last six years, and the fact that it was reprinted several times, were evidence of its value to workers in the field of nutrition.

The war and its associated nutritional problems created a demand for new analytical data. The composition of cooked dishes altered during the war, partly because of the introduction of 85% extraction flour, dried eggs, and dried skimmed milk, and also because rationing led to the adoption of plainer recipes. This did not necessarily lead to the consumption of less nutritious products. After minor modifications and additions in 1942 a new edition of *Chemical Composition of Foods* became necessary. There has been little change in the form of the volume. Information has been brought up to date and figures on new foodstuffs introduced during and after the war have been added. A special feature of the book is that it gives figures not only for uncooked food but also for the same food prepared by various methods. An interesting table is that on the phytic acid content of foodstuffs. The importance of phytic acid is twofold. Its calcium and magnesium salts being insoluble, they are precipitated in the gut if the food contains much phytic acid, and thus not only are calcium and magnesium salts lost to the body but also the phosphorus in the phytic acid.

Food research is not only technically exacting—some 20 constituents have been estimated for each food, and there are over 600 foodstuffs listed—but it is very laborious. Almost every substance analysed brings up fresh problems, and the solution of these may take weeks or even months. Many Ministry of Food recipes using wartime foodstuffs were prepared and submitted to analysis. The number of man hours that went into the making of McCance and Widdowson's book must be phenomenal. It is indispensable not only to the nutritionist but also to the physician, because a knowledge of the chemical composition of foods is the first essential in the dietetic treatment of disease as well as in research on problems of human nutrition.

INTRODUCTION TO HUMAN ANATOMY

An Introduction to Human Anatomy. By Clyde Marshall, M.D. Revised by Edgar L. Lazier, Ph.D. Third Edition. (Pp. 418; 303 illustrations, 13 in. colour. 12s. 6d.) London: W. B. Saunders Company. 1946.

A third edition of Clyde Marshall's book has now been published, the new edition having been enlarged and revised by Prof. E. L. Lazier, of the University of California at Los Angeles, but without any substantial alteration in the general plan of the original work. Certain improvements and differences in the presentation of the subjects have, however, been made, more especially with regard to the description of the joints and ligaments in the chapter on the skeleton, and in the grouping of muscles according to their function rather than the order in which they are usually exposed in a dissection. The description of the circulatory system has also been rearranged on the basis of the principal functions of the system rather than the anatomical relations of the vessels to the surrounding parts. Some new diagrams and figures have been added, or introduced in place of less adequate older figures, more especially in the description of the muscular system and of the optic visual and reflex paths, and the chapter on the endocrine glands, in which recent work on the functions of these organs has been referred to in considerable detail.

The purpose of the book as an introduction to human anatomy, with special stress on the association of structure with function, is thus well fulfilled; a word of warning to

lical students is, however, necessary, for although a knowledge of general principles may be quickly acquired by the use of an elementary textbook, a mastery of the details of human anatomy is essential for both medical and surgical practice; and, however good an introductory textbook may be, such books must be supplemented by the use of the best dissecting manuals, and the study of the classical works on descriptive anatomy and histology.

PATHOLOGY OF THE C.N.S.

Pathology of the Central Nervous System. A Study based upon a Survey of Lesions Found in a Series of Thirty Thousand Autopsies. By Cyril B. Courville, M.D. Second edition, revised and enlarged. (Pp. 450; 208 illustrations, 36s.) California: Pacific Press Publishing Association; London: H. K. Lewis and Co.

The first edition of Prof. Courville's *Pathology of the Central Nervous System* was unusual for three main reasons: it incorporated the results of observation of an enormous mass of pathological material in one centre, it depended to an unusual extent upon the author's own researches, and because of this it presented neuropathology as a living, and therefore progressing, process, the dynamics of which may be misunderstood in its final immobile stage. In the second edition the extension of the author's work on cellular pathology has been included, and the serial diagrams of cellular changes, which are a feature of the first chapter, lend meaning to the later and more orthodox illustrations. It is a pity in this respect that Prof. Courville's recent work on the cellular pathology of brain trauma appeared too late for inclusion in the present edition.

There is a very large chapter, of over 70 pages, on trauma, which is of topical importance. This, like other chapters, has numerous diagrams of the mechanism of the disorder, but some of the diagrams of the mechanics of brain injury have been over-simplified for the sake of clarity. Recent experimental work has shown how very complicated may be the results of the most simple head injury.

This edition, like its predecessor, is really a textbook of applied neuropathology for the practising neurologist and neurosurgeon, rather than for the student of neuropathology. It is intended for general study rather than for casual reference. The additions which have been made to the second edition make it as welcome as the first. The material is attractively presented and the illustrations are excellent.

THE LAW OF PHARMACY

A Textbook of Forensic Pharmacy. By Thomas Dewar, Ph.D., B.Pharm., B.Sc., Ph.C., Barrister-at-Law. (Pp. 253. 10s. 6d.) London: Edward Arnold. 1946.

This is a concise but comprehensive textbook of the law relating to the practice of pharmacy. Much of its information is contained in standard textbooks of medical jurisprudence, but not nearly so fully nor systematically. The author's aim has been to present in a single volume all the forensic pharmacy which is ordinarily taught to candidates seeking qualification as pharmacists, and his book is the first we have seen which fulfils his object. Its first part deals with pharmacy, poisons, and dangerous drugs; its second with medicines; and its third with the law governing retail business. It gives in appendices the text of the Poisons List, the schedules to the Poisons Rules, a list of the poisons the subject of monographs in the *British Pharmacopoeia*, a list of the drugs and preparations exempted from the Dangerous Drugs Regulations, the relevant schedules to the National Health Insurance regulations, and a number of examination questions arranged in order of the chapters of the book. Mr. Dewar does not confine himself to examinations, but covers the subject fairly and fully. His first chapter is a complete account of the constitution and functions of the Pharmaceutical Society of Great Britain and its statutory committee. The test of examination requirements has, however, ensured so far as is practicable that nothing important shall have been omitted, and indeed this book should prove a valuable day-to-day guide to every practising pharmacist. It is good value at half a guinea, but the reader may feel moved to ask whether, in a formal didactic reference book, the Shakespearean quotations at the head of each chapter are really necessary.

Notes on Books

A Laboratory Manual of Anatomy and Physiology, by NELLIE D. MILLARD and MARY JANE C. SHOWERS, of the Michael Reese Hospital School of Nursing, Chicago, and the Christ Hospital School of Nursing, Cincinnati, indicates a departure from the extent and character of the physiological training which has hitherto been customary in the teaching of nurses. The manual consists of a series of drawings, with directions for 30 practical classes in anatomy and physiology, and each is accompanied by a summary in which questions are asked respecting the day's lesson. The drawings, mostly in outline, are intended to help the students in making a record of the demonstrations. These include the study of the human skeleton and dissection of various animals, such as the frog, cat, guinea-pig, or rabbit, or of parts of animals—e.g., a veal or sheep heart, or a pork kidney. The students work singly, or in pairs, and in the physiological section are expected to "pith" or anaesthetize frogs and, after identifying particular organs and nerves, to study the effects of division or stimulation of nerves, or direct stimulation of limb-muscles or parts of the heart; also the effect of drugs, and observations on segmentation and peristalsis of the intestine. Instructions are given on the estimation of haemoglobin and the coagulation time of blood, and there is also an excellent diagram of a haemocytometer, with directions for making blood-cell counts. The nurse's training in Chicago and Cincinnati thus includes much practical work which has hitherto come only within the scope of advanced medical study and in this country has very properly been considered outside the nursing curriculum. The book is published by W. B. Saunders Company at 5s.

A second edition of *Hydrotherapy*, by RUTH M. LE QUESNE and MARY GRANVILLE (Cassel and Co; 7s. 6d.), is welcome. Primarily intended for students working for the diploma of the Chartered Society of Physiotherapy (formerly the C.S.M.M.G.), it would certainly be advantageous to medical students to remind them of what they see in the somewhat cursory official visit to the neighbouring spa or hydrotherapeutic clinic. After preliminary chapters on the history of the subject, on the physical principles involved and a few physiological implications, short descriptions of the usual methods of hydrological treatment are given. A short chapter on "treatment of some common conditions" may be useful, but has the inevitable defects of such very brief summaries of a complicated subject. Finally there is a not too accurate list of the facilities at British spas. For example, it is stated that several of the springs of Bath are rich in radium emanations, and its waters are chiefly used externally. Actually there is no variation in the water of Bath, so that it is all radioactive, for what that is worth, and it is extensively used internally.

Flying Visit (London: Church Missionary Society; 2s. 6d.) is the record, in the form of a diary, of a remarkable wartime journey through West and East Africa and the Middle East by Dr. H. G. ANDERSON, who travelled 26,000 miles in twenty-four weeks to visit missionary establishments in Nigeria, Kenya, Uganda, Sudan, Egypt, Palestine, and Iran. His observations, necessarily fleeting, are full of interest, especially to those in sympathy with missionary work. The book is illustrated by some excellent photographs, and it includes nine relevant maps.

Preparations and Appliances

A SIMPLE DRIP-FEED TYPE OF ANAESTHETIC APPARATUS

Dr. RALPH BIBBINGS writes from Princess Elizabeth Orthopaedic Hospital, Exeter:

The need for a simple anaesthetic unit, suitable for a wide variety of surgical procedures, is one that arises frequently. The following account describes a simple machine that has been devised at this hospital. Already it has been used in some 250 instances, and the results have been most successful.

Description of the Machine

The apparatus has been so designed that it may be easily constructed on the premises of the average hospital from standard parts. The vaporizer consists essentially of a metal canister with a removable lid. I have found that a small "Kodak" developing tank (about 5 in. long) suits the purpose admirably. The bottom and the lid of the canister are each perforated by a single central hole of about 3/4 in. diameter. Into the aperture in the bottom of the canister is soldered a short length (2 in.) of metal tubing over which one end of a length of "concertina" tubing is fitted. The bole in the lid has, arranged on its inner side, a flap of rubber which occludes it. This flap is attached to the periphery of the lid, being

held there between two washers by means of a screw. Thus a simple inspiratory valve is formed. To prevent the valve from sticking and to ensure an airtight closure, the margin of this aperture should be raised. This may be effected by soldering a sharp-edged metal ring about the hole, or else the hole may be made by punching it from the outside instead of being drilled.

Into one side of the can is soldered a small metal tap. In my own model a most satisfactory one was obtained from the local gas company. The vaporizer is now set up as shown in the diagram.

It is mounted on a wooden stand which carries a short upright to which are wired a small glass reservoir and a drip feed window. These are connected by short lengths of rubber tubing. The inside of the canister is now packed with cotton gauze, just so tightly as not to form any appreciable obstruction to respiration. The face-piece, into which the other end of the delivery tube is plugged, is fitted with a standard expiratory valve. Both apertures in the canister are separated from the gauze by perforated zinc diaphragms. These are to prevent cotton gauze from being sucked into the delivery tube and also to prevent the rubber flap valve being fouled by the gauze. The machine is now complete and ready for use.

Action.—The principle of the machine may be gathered from a study of the diagram. Liquid anaesthetic is placed in the reservoir, whence it is delivered to the vaporizer at a controlled rate, the latter being determined by the opening of the stopcock. In the vaporizer, through which air destined for inspiration is caused to pass, the anaesthetic is adsorbed on to a fine gauze mesh. Hence a small quantity of anaesthetic is split up so as to present a relatively large surface area to the incoming air. On expiration, the valve openings are reversed, air escaping through the face-piece valve. This arrangement provides for a high degree of vaporization.

Methods of Use

The apparatus may be used for the administration of either trichlorethylene or ether.

Trichlorethylene may be used for producing either analgesia or anaesthesia. For induction purposes, the mask is closely applied to the patient's face so as to ensure a gas-tight fit, the patient meanwhile being instructed to continue breathing quietly. As there is no appreciable obstruction to respiration, no particular effort is required of the patient. Hence one may pause for a few moments at this stage, for by so doing the patient is enabled to realize that he can breathe without embarrassment, while at the same time a few words of explanation serve to reinforce his confidence. With the patient now at ease and breathing comfortably, the stopcock is opened a trifle, to allow a delivery of some 30 drops a minute. This is of course an average rate for induction purposes. Naturally, it tends to vary with the type of patient, the extent of the premedication, etc. In the robust type, one may require more, but an increase beyond this rate should be made with caution. In most cases it pays to be patient, provided that the airway is good and that breathing is of satisfactory rate and depth. The aim should be to deliver fluid at such a rate that a steadily rising concentration of vapour is produced. It is expedient therefore to avoid trying to hurry a patient by douching, while on the other hand too slow a rate only prolongs the induction unnecessarily. The patient should be aware only of the smell of the anaesthetic. He should never be sensible to its pungency. When the desired level of anaesthesia has been attained, the delivery may be suitably reduced. The depth is

surprisingly and rapidly sensitive to small variations in the rate of flow. In general, I have found that the longer the operating period the more the delivery rate can be reduced. In a robust man, for example, after the first half hour or so, 10-20 drops a minute is usually sufficient for maintenance purposes. The usual precautions must of course be taken in using trichlorethylene. Hence, one must avoid trying to "push" the drug in the hope of obtaining a lower level of anaesthesia. Should that become necessary then the reservoir should be emptied and replaced by ether.

With ether the same methods apply, except that the rate at which ether must be delivered is considerably greater than that required for trichlorethylene. About 90-120 drops are necessary during the induction period, with a maintenance rate of perhaps 50-70 drops a minute.

In general, the machine is more suitable for use with trichlorethylene than with ether, on account of the greater latent heat of vaporization of the latter. However, in spite of this, the results with ether have been very promising. Despite the fact of there being no water jacket, the degree of cooling that takes place brings about but a slight condensation on the outer surface of the canister, even with the delivery rate up to 120.

Types of Operation

There would appear to be few operations for which the apparatus could not be used. So far, its use has been confined to the several types of operation employed in orthopaedic surgery. Fortunately, for trial purposes, this has provided a relatively wide field. Thus the machine has been found effective and useful in obtaining suitable anaesthesia for repair and reconstructive work necessitating the mobilization of muscle and tendon. For incisions and drainage of osteomyelitic cavities, and manipulative surgery in children, the type of anaesthesia obtained has been found exceedingly smooth and uneventful. In the longer operating periods demanded by peripheral nerve surgery, anaesthesia has presented several problems which have been solved through the use of the apparatus. I have found that induction with sufficient intravenous barbiturate to carry the patient into the third stage, followed by trichlorethylene, is the anaesthesia of choice in these cases. The absence of such distractions as the hissing of valves, or the noise made during the changing of cylinders, is a very considerable advantage and one that is much appreciated by the surgeon in operations of long duration. In addition, the machine has been found especially convenient for obtaining analgesia for painful dressings, the removal of packs, drains, etc. Such procedures are often carried out in ward dressing-rooms. In such cases the small and easily transportable machine can be readily available.

Advantages.—(1) Ease of construction. The machine is assembled mainly from standard hospital accessories. (2) Portability. The whole unit, when packed into a small suitcase, weighs only a pound or two. (3) High degree of anaesthesia obtainable. (4) Pleasant induction. (5) Economy. The amounts used are not at all excessive. In established anaesthesia the consumption is at the rate of 10 dr. of ether, or about 4-6 dr. of trichlorethylene, per hour. (6) Remote control. The only control, the stopcock, is situated at a distance from the patient. (7) Silent action. (8) Adaptability to any head position. (9) Incidence of post-operative vomiting is low. After trichlorethylene it is a rare event. (10) No complicated valve for rebreathing mechanism. (11) No hot-water jacket, chemicals, etc. (12) No resistance to respiration. (13) No appreciable increase in dead space. (14) The exact amount of anaesthetic used is known.

Disadvantages.—(1) The exact percentage of anaesthetic vapour is unknown. (2) Inability to reduce vaporization instantaneously: hence the necessity for care being taken against admitting an excessive quantity to the vaporizer.

I wish to express my thanks to Mr. Norman Capener, F.R.C.S., for his encouragement and the interest he has shown during the development of the apparatus.

"BENADRYL"

Parke, Davis and Co. are now supplying capsules containing 50 mg. "benadryl," which is a substance having the property of neutralizing the action of histamine in many directions, and which is therefore recommended for the relief of allergic symptoms. It has a spasmolytic action also, which is not surprising in view of the similarity of its chemical structure to that of other spasmolytic substances. Its chemical name is β -dimethylaminoethyl benzhydrol ether hydrochloride. Benadryl is to be taken four times daily by patients with acute or chronic urticaria and by those with hay fever. It is also of use in drug sensitization. The clinical reports are very promising.

Hanovia Ltd., of Slough, Bucks, have prepared a treatment record card for the use of light clinics and practitioners for systematic recording of actinotherapy applications and results. These cards cost 6s. for 50 and proportionately much less for larger quantities.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 3 1946

THE REPRESENTATIVES AND THE BILL

the Annual Representative Meeting was held last week at M.A. House and completed its business in two and a half days. A report of the proceedings appears in this week's Supplement, and at page 168 of the *Journal* we print in full a statement by Dr. H. Guy Dain, the Chairman of the Council, on the National Health Service Bill. The Special Representative Meeting in May, coincided with the debate on the Second Reading in the House of Commons, and last week's A.R.M. coincided with the Report Stage and the Third Reading, accounts of which appear in this week's Parliamentary Notes. The dominant theme before the Representative Body was the National Health Service Bill, and the principal variation on this was Dr. Dain's speech. He reminded the Meeting that when they met Mr. Ernest Brown three years ago the Ministry of Health had ideas for a whole-time service. By discussion and negotiation they went some way to agreement both with Mr. Brown and his successor, Mr. Willink, on the disadvantages to the public of a whole-time service. When they succeeded in making contact with Mr. Aneurin Bevan they found that he had practically adopted the framework of the service as left by Mr. Willink, but had added to it the principle of nationalization. It was this that made such an enormous difference to the medical profession. Mr. Bevan had refused to negotiate or to talk on the principles on which the Bill was founded: these were the State ownership of hospitals, the destruction of the goodwill of general practices, the direction of practitioners, and the payment of practitioners, in part at least, by salary. These were the steps by which the Government proposed to take the practitioner under control in a State service. Not one of them was necessary to the efficiency of the service and served no purpose except to carry out Socialist ideals. Dr. Dain considered that neither voluntary nor local authority hospitals had fully understood the position of national ownership of hospitals. There would be no possibility of practice by consultants and specialists outside the new service, for they could not practise without access to beds, and all beds would be under control of the Minister, the owner of all the hospitals. "Thus an important section of our profession will become, for practical purposes, servants of the State almost immediately, and their opportunities for independent practice will be infinitesimal." Dr. Dain reminded the Meeting that when they discussed the compensation figure with the Minister they clearly stated that this was not to mean that they admitted the principle of forfeiture of goodwill. They had maintained that the general practitioner in a national service should be employed by and responsible to the patient; they were, therefore, opposed to payment by any form of

salary, which meant the transference of the practitioner's responsibility from the patient to the person who paid the bill. The Minister had appreciated that the principle of free choice by patients would be interfered with by a salaried service. Dr. Dain observed that the Bill contained many excellent points, but on the Report Stage the Minister had not conceded the right of every practitioner to come into the Service if he wished—a right conceded to the profession in 1911. "Nor has he conceded, what we should certainly require, the right of appeal from a decision of the Minister which would take the doctor out of the Service." In the progress of the Bill through the House of Commons the Minister had maintained the complete right to do everything himself. "He is the complete and uncontrolled dictator." The Minister was to determine every committee and council set up under the Act and even have the power to elect the chairmen of those various bodies. This meant that the appointments would be made on the advice of the Civil Servants—"and we ourselves will be employed by and dictated to by the Civil Servants straightaway, and our freedom in many respects will disappear."

Dr. Dain reminded the R.B. that last May they decided (1) that there should be no direction of medical men, (2) that they were opposed to State ownership of hospitals, (3) that doctors should retain the goodwill of their practices, and (4) they were against any modification of the method of remuneration by capitation fee. "Now we have come to the time when one side or the other has to give way. A conflict is inevitable." Decision would have to be made by each individual member of the profession, and the Council would act on their instructions. The first problem was whether there should be negotiations unless the principles of the profession were conceded. They therefore had it in mind to invite every practitioner on the *Medical Register* to state whether he wished negotiations on the regulations of the Act to take place or whether there should be a refusal to negotiate. The latter would mean a refusal to take part in the Service whatever the form of the regulations. He hoped they could get a straight question put to the profession—"it is up to us to know exactly what is the opinion of the people who have sent representatives to this meeting." It was true they could not foresee the precise form of the Act, which had yet to go through the House of Lords, but it would be an advantage to proceed on the assumption that no very material change was likely. Dr. Dain concluded by referring to the recent broadcast by the Lord President of the Council, Mr. Herbert Morrison, in which he said that the Government was out for planning with liberty and order with freedom. "That," Dr. Dain continued, "is just exactly where we ourselves stand, and if we look at the Lord President's speech concerning the Press a few days later we shall begin to wonder whether on the occasion of that broadcast he was not talking with his tongue in his cheek." In a later contribution to the debate Dr. Dain said that if they went into negotiations in detail they would be giving way on their principles. It was essential to know before very long the attitude of the profession on the question of adherence to the principles.

The discussion which followed the Chairman of Council's statement showed the Meeting's high appreciation

of his able speech and agreement with the main issues raised in it; and also widespread uneasiness over the course of events since the present Government came into office a year ago. One speaker, however, doubted whether any section of the community should flout the law and drew attention to the difficult position in which "the average general practitioner" would be if he refused to work the Act. He claimed that what mattered to the majority of the general practitioners in this country was whether they were going to have a living wage. Another speaker asked whether, as the progress of medicine and the welfare of the patient was the proposed objective of the Government, they could not "play together in the same team." In connexion with one of Dr. Dain's statements Dr. J. A. Brown intervened that he was sure Dr. Dain had no intention of making this a political issue. "Their action had nothing to do with their politics; the only consideration was the health of the nation and the freedom of the profession." Dr. R. G. Gordon remarked that in relation to consultants and specialists Mr. Bevan had tried to split the profession. Many consultants and specialists found his hospitals proposal attractive. Other speakers observed subsequently that many consultants and specialists were already taking part in discussions on the constitution of Regional Boards.

It will be recalled that the Special Representative Meeting last May decided that a referendum of the medical profession should be taken at an appropriate time. After much discussion the following motion was put to the Meeting and carried:

That a referendum of the whole profession should be taken soon on the simple issue of whether negotiations on regulations with the Minister should take place or not, and that the Meeting recommends to the Council the desirability of the plebiscite including personal contact with each member of the profession as soon as this can be arranged.

It will be noted that the Resolution includes the two words "plebiscite" and "referendum," and doubt as to the exact meaning of these two words was expressed at the Meeting. It may, therefore, be appropriate here to give the relevant definitions from the *Shorter Oxford English Dictionary*: "Referendum" is defined as "The act, practice or principle (chiefly associated with the Swiss Constitution) of submitting the direct decision of a question at issue to the whole body of voters." "Plebiscite" defined as "A direct vote of the whole of the electors of a state to decide a question of public importance; also by extension, a public expression, with or without binding force, of the wishes or opinion of a community." It seems, therefore, that in the particular matter at issue the extended definition of "plebiscite" is the one which applies. If no serious challenge to the Government is offered by the House of Lords when the Bill passes to it we may expect the present amended Bill to become an Act in the early autumn. The Council of the B.M.A. now has an instruction from the Representative Body to take a plebiscite soon on the question whether or not the medical profession is to enter into negotiations with the Minister of Health on the regulations which will embody the terms and conditions of service in the Government's National Health scheme. Each doctor on the *Medical Register* will have to make up his own mind, and whichever way he

casts his vote he will be making a grave decision both for himself and for his colleagues. It is not a decision that can be made by a toss of the coin but only by a fully considered and dispassionate examination of the numerous personal and communal issues raised by Mr. Bevan's Bill. When the collective view of the whole profession is known then the Council of the B.M.A. and the Negotiating Committee will be in an unassailable position in relation to their conduct with the Minister of Health. If the profession decides that negotiations on regulations should be entered into, then it will reserve its decision on whether or not to enter the new Service until the details of the main regulations are known. If it decides not to negotiate on regulations, then a position will be reached in which a prolonged and bitter conflict will be waged between the present Government and a highly important section of the community without whose willing co-operation the Health Service Act will remain a "dead letter." The decision, we repeat, rests with the individual members of the profession.

CONSOLIDATION AND UNITY

There has been no Annual Meeting since 1939, and, though once more there was no Annual Meeting this year, there was a touch of ceremony in the introduction of a new President, Sir Hugh Lett, who succeeds a veteran in B.M.A. counsels, Mr. H. S. Souttar, who with the conclusion of his Presidential year completes the remarkable record of having been successively Deputy Chairman and Chairman of the R.B., Chairman of Council, and President of the Association. A demonstration of loyalty to the Association in another form was shown by the presence on the platform of representatives from Australia, South Africa, and New Zealand, and by the short addresses of comradeship and good wishes from representatives from India, Jamaica, Ceylon, Malta, and Assam. In particular we may welcome the desire of South Africa to maintain the friendly links that bind it to the parent body in spite of its formal grouping into a separate identity.

In his brief but cogent Presidential address, which appears in the opening pages of this week's *Journal*, Sir Hugh Lett brought into narrow focus all that our profession has gone through since September 3, 1939. He paid a much-deserved tribute to the research work of medical scientists which has played such a vital part in achieving victory over the enemy, and to the work done on the Home Front by the E.M.S., by the rank-and-file of the profession, by the medical officers of health, and by the Central and Local Medical War Committees. In the short time at his disposal Sir Hugh inevitably had to omit much that he might have said. This lends extra stress to what he has included, and we therefore welcome his thoughtful observations on the relationship between the Royal Colleges and the B.M.A. Sir Hugh recorded that in 1938 Dr. G. C. Anderson, then Secretary of the Association, was invited to serve as liaison officer between the Committee of Reference of the Royal Colleges and the Central Medical War Committee. In 1940 the B.M.A. invited the Royal Colleges to review with it the peacetime organization of the general medical and hospital services and secured their eventual co-operation in the work of the

Medical Planning Commission. This co-operation, along with that of other bodies, continued in the highly important deliberations of the Negotiating Committee, which is still in being and still has important functions to perform. Sir Hugh observed that these are critical days, and the need for co-operation in preserving the unity of the profession will in the coming months be greater than ever. "It is," he concluded, "only by working together, consolidating our profession, and making it as strong as possible that we can protect the sick and maintain the proud position of British Medicine, together with all those things tangible and intangible for which it stands."

FIBRIN FOAM AND FIBRIN FILMS

The fractionation of human plasma proteins, and the chemical and biological properties of its products, have been widely studied by workers in the department of physical chemistry of the Harvard Medical School.¹ A method has been elaborated there for the preparation of human fibrinogen and thrombin on a large scale. On a small scale Dickson Wright collected sheets of fibrin as early as 1940 and used them to line the cavities left after the removal of brain tumours. He described his experiences in a paper entitled "Blood Fibrin as a Styptic" at the twenty-eighth meeting of the Society of British Neurological Surgeons in Oxford on July 19, 1941. Fibrin may now be employed surgically as fibrin foam or as fibrin film, the latter taking the form of sheets, fibres, or seamless tubes. Ferry and Morrison² have also described a fibrinogen plastic which can be moulded under the action of heat and which may prove of value in ophthalmology and plastic surgery.

Fibrin foam is a spongy material which becomes an effective absorbable haemostatic when soaked in human thrombin solution. Ingraham and Bailey³ found it a valuable styptic in cranial surgery. Three bottles contain in sterile form the necessary materials—fibrin foam, dry thrombin, and physiological saline. At the time of operation the saline is added to the thrombin, and strips of fibrin foam, cut to a suitable size and shape, are placed in the resultant thrombin solution, which they rapidly absorb. Gauze is used to press the soaked foam gently against the bleeding brain surface, and the excess of moisture is removed by suction. Larger masses of foam may be needed to fill post-operative cavities, but the clotting process is required only at the interface between fibrin and tissue, and the central portion of such a mass may be removed before closure of the wound. The presence of fibrin during healing provokes virtually no foreign-body reaction and does not increase the size or density of the resultant scar. A large mass of fibrin may aggregate fewer foreign-body giant cells than a single linen suture. In the abdomen it does not stimulate peritoneal adhesions. Bailey, Ingraham, and their co-workers⁴ have employed fibrin foam successfully to arrest haemorrhage from the liver bed after cholecystectomy; from the cut surface of the liver after trauma, biopsy, and removal of a tumour; from pancreas or spleen after biopsy of these organs; from the prostatic cavity after prostatectomy; from tooth sockets after dental extractions; and from bleeding surfaces prepared for plastic procedures. It is effective in stopping bleeding from the surface of a lung separated from an adherent chest wall and from the walls of the cavity left after enucleation of a mediastinal

tumour. A thin sheet of fibrin foam applied to a bone-end after amputation readily controls haemorrhage from it and reduces the risk of haematoma formation in the stump. It is especially valuable when there is local haemorrhage during operations on haemophilic patients. Fibrin foam seems to be contra-indicated only in the case of bleeding from the pharynx. An anaesthetized patient may inhale fragments of the material, and these might produce plugging of the bronchi.

Fibrin film, in fine transparent sheets sterilized by glycerol or, more conveniently, by heat, is rather brittle in the dry form in which it is stored, but after immersion in saline for fifteen minutes and manual stretching to twice its original area it develops all the properties of a moist membrane. It has been applied by Ingraham, Bailey, and Cobb⁵ as a substitute for dura in 94 cranial operations and has produced no undesirable effects. Stimulating little fibrous tissue reaction, it serves as a neo-membrane to close operative or post-traumatic dural defects without the production of meningo-cerebral adhesions. A piece of film rather larger than the defect to be closed is insinuated under the cut edge of dura. The material has been highly praised for its value in the operative treatment of post-traumatic epilepsy.

Fibrin has also been applied to the repair of divided peripheral nerves. Seddon and Medawar⁶ described a method (fibrin suture) of maintaining the apposition of the trimmed nerve-ends by a fibrin clot, provided the gap between the ends was inconsiderable. Singer⁷ has elaborated this technique, using 2% fibrinogen as the adhesive material and enclosing the nerve-ends and the fibrinogen in a tube of fibrin film.

VIBRIONIC FOOD POISONING DUE TO MILK

A very unusual type of food poisoning, affecting the inmates of two institutions in Illinois, is described by Dr. A. J. Levy.⁸ The total number of cases was 357, of which 151 were admitted to hospital. The outbreak lasted 13 days. The duration of illness ranged from two days to two weeks, the commonest being 3-5 days. Among the prominent symptoms were fever to between 99 and 102 °F. (37.2 and 38.9 °C.), diarrhoea, and general prostration; the additional occurrence in many cases of nausea, vomiting, abdominal cramps, general malaise, and aching of the head and limbs suggested a diagnosis of intestinal influenza. Investigation narrowed down the probable cause to the milk supply. There were two sources of milk to the institutions: one, a home-produced pasteurized supply; the other, supposed to be pasteurized but delivered by a dairy that handled both raw and pasteurized milk in identical unlabelled containers. Illness was confined to consumers of the second supply and was probably due to the consumption of raw milk that had been carelessly substituted for pasteurized. As soon as boiling of the milk was introduced the outbreak ceased.

Bacteriological examination of the vomit and faeces of patients failed to reveal any of the usual causes of food poisoning or enteritis, and agglutination tests put up with sera from six convalescent patients against a wide variety of organisms yielded negative results. Smears from the faeces, however, showed the presence of vibrios in 31 out of 73 specimens, sometimes almost in pure culture. Though these organisms could not be grown from the faeces, they were isolated by blood culture from 13 out of 39 patients studied. The organisms resembled cholera vibrios morphologically but differed from them in other respects. They

grew in tryptose phosphate beef broth but not on any solid medium till after 30 subcultures, and then only very poorly. No sugars were fermented, and no indole was produced. These characters resemble those of *Vibrio fetus*, an organism isolated by McFadyean and Stockman⁹ in 1913 from the uterine exudate of aborting sheep, and even more closely those of *Vibrio jejuni*, an organism described by Jones and Little¹⁰ in 1931 as probably responsible for a diarrhoeal disease of cattle known as winter dysentery or black scours. Injection of rabbits and pigeons intravenously and intramuscularly was without effect; so also was feeding of cultures to kittens. However, intravenous injection of 3 ml. of a broth culture into a dog was followed in 24 hours by severe diarrhoea, which ended fatally; vibrios were seen in the liver and spleen on direct smear. Attempts to probe into the history of the animals on the farm from which the milk was derived were met with opposition on the part of the farmer, so that it was impossible to attribute the infection of the milk to illness among the animals. The circumstantial evidence incriminating the milk was, however, very strong, and the demonstration of vibrios in the patients' faeces and their cultivation from the blood leaves little doubt that these organisms were responsible for the outbreak.

SURGERY OF THE AORTA

Astley Cooper first performed ligation of the aorta in 1817, after much careful thought and animal experiment. Although his patient died after two days, the operation has been successfully performed since on at least two occasions. It has fallen to Crafoord,¹¹ of Stockholm, whose outstanding contributions to thoracic surgery are already well known, to perform successfully resection of the strictured aorta with restoration of continuity by direct end-to-end anastomosis for the relief of congenital coarctation. In February of this year, at the Royal College of Surgeons, he delivered a simple, even diffident, account of his dramatic operation.

Crafoord had already demonstrated in dogs that provided the blood supply to the brain was maintained (by anastomosis between the carotid and jugular vessels of another dog) the flow of blood to the other organs could remain suspended for as long as 25 minutes without signs of organic damage. On the strength of this, when operating for patent ductus arteriosus, he applied clamps so as to enable him to divide the duct and suture the aorta. In one patient the aorta was shut for 27 minutes, and no ill effect was noticed. In congenital coarctation a free collateral circulation already exists. Crafoord considered, therefore, that in such cases he might with safety keep the aorta closed for a much longer time while resecting the strictured portion. Two suitable patients presented themselves in 1944, a boy of 12 and a man of 27. Thoracotomy was performed to examine the feasibility of resection. In both cases it was found possible to mobilize the aorta, resect the stricture, and approximate two ends of equal size without tension, so as to allow end-to-end anastomosis. Both patients made a good recovery, and up to the present Crafoord has performed this operation nine times with only one death.

In these first two cases the blood-pressure in the upper and lower limbs returned to normal after the operation. This is important, for the main reason for correcting the aortic stricture is to relieve the hypertension in the head and upper limbs, which is the chief cause of death. The abnormality is fairly common. Maud Abbott, in her

classical work on congenital heart disease, found 142 instances in 1,000 cases of congenital cardiovascular defects. The average age at death in her series was 32, with extremes of 3 and 92 years. While it is true that occasional cases are seen late in adult life, it is generally accepted that most patients die young. If hypertension is detected in a young adult, aortic coarctation must be thought of, and sought for. In this way the possibility of surgical relief may be held out to more sufferers from the condition. Crafoord is to be congratulated on a brilliant contribution to cardiovascular surgery.

MEDICAL GEOGRAPHY

The relation of climate (and activities correlated with climate) and disease was one of the earliest topics of scientific inquiry; for us, Hippocrates was the pioneer. Medical geography was extensively studied by our great-grandparents and grandparents, but general medical interest in it has rather faded owing to increasing knowledge of biological and biochemical factors of diseases with well-defined geographical distributions. In a thoughtful essay Dr. Richard Upjohn Light¹ points out that geographical problems remain to be solved, that the new knowledge has not diminished their importance but increased our chance of solving them by eliminating, or defining, associated factors. He also notes that in this age, when "No place on earth is more than 60 hours from your airport" is almost a true statement, geographical knowledge of possibilities becomes practically important. The American Geographical Society has long felt the need for organized research in medical geography and organized a conference on its feasibility. This reprint includes an account of the conference, at which various opinions on methods were expressed, although no speaker questioned the importance of such an undertaking. Attention was given to cartographical considerations, especially by Dr. J. K. Wright, whose principal arguments are summarized. This pamphlet should interest many readers, particularly those in the Colonial and fighting Services.

SOYA BEAN: AN INDIAN REPORT

Report on Soya Bean, by the Soya Bean Subcommittee of the Nutritional Advisory Committee, Indian Research Fund Association, has been received from New Delhi in pamphlet form.² This report deals with investigations made in Indian laboratories on the nutritional value of the soya bean. The general conclusion drawn from these investigations is that although the bean contains more fat, minerals, vitamins, and available proteins than the native pulses eaten as food, it is not superior to these in growth-promoting qualities. It is superior to rice but inferior to milk in this respect, and it is also deficient in the essential amino-acids—cystine and methionine. In spite of these findings soya bean may prove a better food supplement than pulses for typical Indian diets, which are quantitatively inadequate and consist largely of cereals of poor nutritive value such as rice. The subcommittee initiating the investigations does not advocate the immediate extension of soya-bean production in India to replace native pulses in the diet. It realizes, however, that the bean is of considerable industrial importance in such countries as the United States as a source of fats, margarine, plastics, and cattle food, and that the part it might play in this direction in Indian industry and agriculture is worthy of investigation.

SOME ASPECTS OF MILITARY OTOLARYNGOLOGY

BY

R. B. LUMSDEN, M.B., F.R.C.S.ED.

for Assistant Surgeon, Ear, Nose, and Throat Department, Royal Army, Edinburgh; Formerly, Lieut.-Col., R.A.M.C.; Adviser in Oto-rhino-laryngology to Middle East Force

years of war service as an otologist, of which 4½ years were spent abroad, have afforded ample time and material on which to base a review of some aspects of otolaryngology in the Army and to consider certain features which might be applied to advantage in future peacetime practice. An analysis of this material is being published elsewhere (Lumsden, 1946).

Chronic Suppurative Otitis Media

This has undoubtedly been the outstanding problem with which Army otologists have had to deal. During a period of months (October, 1943, to December, 1944) 59,368 outpatients were seen by otologists in the Middle East; 35,741 were new patients, and 19,314 (54%) of these were aural cases, a large proportion of which suffered from chronic otitis media (figures are not available). During the same period 8,263 ear, nose, and throat cases were admitted to hospital; of these 1,377 (15%) were suffering from this condition. Of all new outpatients attending one general hospital 19.4% were ear, nose, and throat cases.

At the outbreak of war, instructions regarding Army medical categorization in respect of chronic otitis media and deafness were found to be very meagre. In course of time more precise standards were laid down, and it came to be recognized that the correct management of these cases can save many man-power hours and relieve the Medical Services of much unnecessary work. But chronic otitis media apparently continued to be overlooked with great frequency.

While it has to be accepted that in time of war man-power requirements are such that all cases of chronic otitis media cannot be excluded from the Army, very many were found to be unable to stand up to service in the field, where the majority became unfit on account of an acute exacerbation or superadded otitis externa. This conclusion is the outcome of experience of cases from the Western Desert and also from the Syrian campaign, where a considerable part of the force fought over country which bore little or no resemblance to desert. On the other hand, they remained reasonably fit while employed on base duties, where living conditions are more normal and where adequate attention was available. In the Middle East it was eventually agreed that all cases of chronic otitis media should be "weeded out" of combatant units and sent to communication troops, that they should be regraded accordingly by an ear-nose-and-throat specialist and recommended for employment which facilitated their attendance for regular treatment at an established E.N.T. treatment centre (see below). Such cases could be up-graded or moved from each of such facilities only with the written approval of an ear-nose-and-throat specialist; and they were forbidden to swim. In spite of these provisions, it is my opinion that no man with chronic otitis media (or externa) should be required to serve in a hot climate if it can possibly be avoided.

It has been suggested that, in the Army, sufferers from chronic otitis media are prone to make the most of their disability. Such an attitude has been found to be exceptional, and it was not an everyday event for men to ask if it was not possible for them to be up-graded.

E.N.T. Treatment Centres

As Collins (1943) has already stated, it was suggested that aural treatment centres should be established in reception stations or medical inspection rooms at the larger base camps in the Middle East. This scheme was adopted, and I was associated with their formation and subsequently paid repeated visits to most of them. A few small items of equipment were supplied, including a forehead mirror. Suitable orderlies (of any medical category whenever possible) were given four to six weeks' intensive training in the ear-nose-and-throat departments of neighbouring hospitals. If considered proficient, they then

proceeded to work under the supervision of the medical officer in charge of the camp medical establishment, who maintained a close liaison with an otologist at a near-by hospital, where the cases were seen by him at intervals. The essential factor in the success of the scheme was that these orderlies were not transferred to other duties without exceptional reasons. They were proficient in the use of the forehead mirror, invariably showed keen interest in their work, and the treatment provided was of a high standard. As many as 70 cases have been in daily attendance by appointment, so that loss of working time was minimal. Medical officers quickly showed enthusiasm for the scheme, while patients frequently expressed their appreciation. Apart from other considerations, the number of ears which became quiescent or healed was impressive. Banham (1944) has shown what can be done by such measures in the appropriate types of case.

Chronic otitis media becomes a more difficult problem in the Army because, though the life is frequently healthier, living conditions and facilities for management are more difficult and the antisocial character of the complaint is probably more noticeable. The associated deafness must never be ignored when considering this condition.

Chronic Otitis Media in the Civilian Population

The adoption of a similar scheme in the future Health Service is suggested. Such treatment centres, in addition to school clinics, could be incorporated in health centres and factory clinics. *Special training for nurses undertaking this treatment would be a primary essential.*

The fundamental problem, however, remains that of prevention by ensuring adequate treatment of acute otitis media. Compulsory notification might do much to make the general public more "ear conscious."

Traumatic Affections

Accidental as well as battle injuries have formed a most important part of one's work in the Army. Cairns (1945) has drawn attention to the desirability of close collaboration between the neurosurgeon and the maxillo-facial, otorhinological, and ophthalmic surgeons. It is frequently considered that the otolaryngologist has little or no part to play in relation to traumatic affections, and several factors are responsible for this. But in such conditions as, for example, skull fractures involving the ear or paranasal sinuses he is often found to fill an important role (Lumsden and Fleming, 1944; Lumsden, 1945).

Summary

Problems concerning chronic suppurative otitis media in the Army are discussed and a scheme for the management of cases is described.

A similar scheme is suggested for the civilian population.

Attention is redirected to the role of the otolaryngologist in relation to traumatic affections.

The Minister of Labour and National Service has given notice in the *London and Edinburgh Gazettes* that he proposes to make Special Regulations, regulating certain processes in the manufacture or decoration of pottery. The proposed Regulations would supplement the provisions of the existing Pottery Regulations, and in particular would prohibit the use of glazes other than "leadless" or "low solubility" glazes and restrict the use of ground or powdered flint or quartz in factories where the manufacture or decoration of pottery is carried on. They take the place of the previous draft Pottery (Health) Special Regulations published in February last, to which certain objections were made. The revised draft contains amendments designed to meet some of these objections, particularly in regard to the use of the process known as "dry mixing."

NATIONAL HEALTH SERVICE BILL

STATEMENT BY DR. H. GUY DAIN, CHAIRMAN
OF COUNCIL

In view of its importance, we print below in full the statement made by the Chairman of Council in the debate on the National Health Service Bill at the Annual Representative Meeting last week.

The discussion on this is reported in the Supplement.

Yesterday I moved the adoption of the preliminary sections of the Annual Report of Council, but I reserved until this morning any reference to the National Health Service Bill. I did this for the particular reason that before we discussed items in detail we should devote a little time to the consideration of the position as it is developing. The Bill has passed through its committee stage and report stage, and is due for third reading on Friday next. During these various stages we have seen minor modifications in its structure, but nothing to change the main principles on which it is based. It would be desirable to look at the way in which the Bill has emerged from these discussions. If we go back to our experience of three years ago, when we met Mr. Ernest Brown, we found that the Ministry had ideas for a whole-time service. By argument and negotiations and pointing out the disadvantages to the public of such a service we did get a certain way towards agreement both with Mr. Brown and with his successor, Mr. Willink. Then we had a General Election in July of last year and a new Government whose policy is nationalization.

The Government has proceeded to implement its idea in a number of forms. With regard to the Health Service, for a long time the Minister did not talk to us on that subject because he was busy with housing, and when we did eventually come into contact with him we found that he had practically adopted the framework of the Service as left by Mr. Willink and had added to it the principle of nationalization, which makes such an enormous difference to us. He has refused to negotiate, he has been willing to talk on anything else, but not on the principles on which the Bill is founded.

The principles that are introduced in the Bill are the State ownership of hospitals, the destruction of the goodwill of general practices, the determination to direct practitioners where they shall not go and prevent them from moving without permission, and their remuneration, in part at least, by salary. These are the steps by which it is proposed by the Government that the medical practitioner shall be taken under control in a State Service. None of those additions to the scheme will in any way improve the service to the patient. (Applause.) There is not one of them that is necessary to the efficiency of the Service. They serve no purpose except to carry out Socialist ideals. We should look closely to-day at the effects of those proposals. The first and perhaps the most obvious is the ownership of hospitals. Hospitals have not contested this matter in the way in which I should have thought they would be certain to do. On the part of neither local authority hospitals nor voluntary hospitals has there been a real understanding of the position. The first effect, so far as we are concerned, is that there can be no possibility of practice by consultants and specialists outside the new Service. The Minister will own all the hospitals. No consultant or specialist can practise without access to beds, but beds, both public and private, will be under the control of the Minister, who may at any moment decide whether they shall in fact continue to be public or private. Thus an important section of our profession will, for practical purposes, become servants of the State almost immediately, and their opportunities for independent practice will be infinitesimal.

As to the general practitioner, there are three respects in which he will be brought under control. He is not to be allowed to buy or sell practices—that is to say, he loses the goodwill of his practice and the power to transfer his practice when he wishes to leave the neighbourhood or to retire. The Minister says that he is prepared to compensate for the loss of such goodwill, and he has fixed a sum of £66 millions as being the value of the practices for compensation purposes. When we discussed that figure with him we made the specific

statement that we were not in any way implicated in the principle of forfeiture of goodwill. The Minister demanded these powers in order that he might be able to distribute practitioners. Sometimes the Minister's powers in this respect are discussed rather lightly. It is said that there is no active direction, and that the practitioner entering practice or desiring to change his area is merely told where he may not go. For this purpose he has to get the consent of two Committees and a central body. I would only remind you that this is an "easy" commencement of control. ("Hear, hear.")

We have said that the general practitioner in a national service should be employed by and responsible to the patient, and we are opposed to payment by any form of salary which means the transference of the practitioner's responsibility from the patient to the person who pays the bill. The Minister has appreciated that the principle of free choice by patients—a public matter in which he could not afford to offend—would be interfered with by a salaried service. He is not, therefore, proposing the distribution of patients, but he does propose to pay doctors in a certain proportion by salary, so that he will have a new form of control over the general practitioner. He has said that he does not think the medical profession are ripe to become salaried officers of the State or civil servants. I hope we are not. (Applause.)

We agree that many points in the Bill are excellent. Indeed, we had a part in fashioning them. But it will be seen that on the Report Stage the Minister has not conceded the right of every practitioner to come into the Service if he wishes—a right which was conceded to our predecessors in 1911 in the case of national health insurance. Nor has he conceded, what we should certainly require, the right of appeal from a decision of the Minister which would take the doctor out of the Service. (Applause.) We cannot possibly agree to a national Service covering all people and all doctors in which the last word as to whether a man may practise in the Service or—what amounts to the same thing—in his profession, will lie with the Minister of Health. (Loud applause.) Whatever else we may or may not do, I hope there will be no question as to our determination on that point.

It is interesting to see that in the progress of this Bill through the House of Commons the Minister has maintained the complete right to do everything himself. He is the complete and uncontrolled dictator. He will determine the constitution of every committee and council that is to be set up under the Act. He has not even allowed to escape from his power the election of the chairmen of those various bodies. It is allowed to none of them to have the sense, wisdom, or the opportunity to elect their own chairmen. Is it wise that we should let ourselves into a Service on those terms? (Loud cries of "No.") The Minister says that if he can do it all himself it will retain flexibility in the Service, and he opposes changes which will limit his powers in appointing committees or their chairmen and so put him into a "strait-jacket." But how can he know all the committees of the country and all the people who should be chairmen of them? Surely it is an indefensible position for a Minister to take, and I hope we shall not agree to it, because what it means is that appointments will be made on the advice of the civil servants, and we ourselves will be employed by and dictated to by the civil servants straightaway and our freedom in many respects will disappear.

We said, before the Bill itself appeared, that we considered that the Service should be built up on certain principles. We have laid down principles which establish the freedom of the public and of the profession. The Minister, of course, has the opportunity of hearing the sort of things that we say in public at meetings like this and at meetings in the areas, and his reply is that these doctors are delightful people, excellent at their job, but that when it comes to the field of organization and medical politics they are just foolish, putting forward principles and laying down opinions which are airy nonsense.

That is the position in which we stand with the Minister at this moment. We have adopted our principles, and what I have said is a fair statement of the value which the Minister attaches to them.

In May last we had a special meeting of this Body, and that meeting did four things: (1) it decided that there should be no control over doctors with regard to the areas in which they practise; (2) it decided against State ownership of

pitals; (3) it decided that doctors ought to retain the good- of their practices; and (4) it was against any modification the method of remuneration by capitation fee. The voting each of these four points was as follows: 214 to 2, 210 to 229 to 12, and 209 to 8. Those are substantial majorities which represent the opinion of this Body at that date.

Inevitable Conflict

Now we have come to the time when one side or the other has to give way. A conflict is inevitable. (Applause.) The Minister had the wisdom of the Government of South Africa and had called us into consultation as to the form which the new arrangement should take and had invited us to approve of it before it went to the House of Commons, we should find ourselves in a very different position day. If the Government of one of our Dominions can show it amount of sense, it is a pity that the Government of the other country cannot do the same. (Applause.) This is the time when we have to decide what action we shall take and what stage we shall take it. Do we stand by the decisions of the meeting made in May? (Loud cries of "Yes.") What is the result of this? The decisions that were made in May were in accordance with the instruction by this Body to the Council, and the Council has no authority to modify or alter them in any way until the Body itself alters them. It is impossible for the Council to have any part in the preparation of regulations until the Representative Body gives them a definite authority. The question has already arisen on the application of the Insurance Acts Committee for an increase in the capitation fee for insurance practitioners. They were met by the Minister himself with a statement that that matter could not be separated from the terms of service under the forthcoming Act, and he was not prepared to discuss the insurance capitation fee until the other matter had been discussed as well. He was thereupon told that the Representative Body was against any form of basic salary. He himself has stated his adherence to the principle of basic salary for every practitioner, and so we are precluded entirely from discussing terms of service under those conditions. That is the position which has arisen and which will arise more particularly in the next few months.

All this entails a consideration of the value of our statements and of the expressed opinion of the profession in carrying out what has been decided. The Minister has constantly said that we are a divided profession and that this has become a political question. Some of us are Socialists and some are not. It may be that those who are Socialists will be prepared to accept and work the scheme because it embodies the socialistic principle. But there are others of us who are not Socialists and who think that such a change would be a great disadvantage to the service which the public would get. They are not prepared to join in "on those conditions. (Applause.)

Where do we stand? This decision has to be made, not by the medical profession as a body or acting through the Council, but by each individual member of the profession. We have done what we can to make the position understood to the doctors in the various areas, and through the *British Medical Journal* we have endeavoured to keep doctors informed of the situation. But there comes a moment at which the doctors themselves must be asked what action they intend to take. The Council will act on their instructions and not without.

The first problem to arise is whether there should be any further negotiations at all unless the principles are conceded. We have it in mind, towards the autumn, to invite every practitioner on the *Medical Register* to say whether he wishes any negotiations to take place on the matter of regulations and the drawing up of the scheme or whether he wishes us not to take any steps in that regard, it being understood that the latter decision means a refusal to take part in the Service whatever form the regulations may take. We can get a straight question like that across to the profession, and I hope we can get a straight answer, and it is up to us to know exactly what is the opinion of the people who have sent representatives to this meeting. It is continually put to me that it may be that this Representative Body does not represent the profession. For my own part I am prepared to stand by the decisions of this

Body. We are not prepared to believe that the representatives come here and vote for things, as they did last May, for which they have no authority in their constituencies. But the effect of the influence of representatives in their own constituencies must not be lost sight of at the time this vote is taken.

Some have thought that members of the profession may be tempted by the offer of generous terms. I do not want to anticipate what will be told you by the Insurance Acts Committee later in this meeting as to the Minister's proposals concerning the increase in the capitation fee, but if those proposals are an earnest of the terms which are to be offered under the new Service they are certainly not generous. I think there may be some discussion as to the date on which the specific questions should be put and a Special Representative Meeting called. While it is true that we cannot foresee even now the precise form of the Act, which has yet to go through the House of Lords, it would be a great advantage to proceed on the assumption that no very material change is now likely, so that we may get the questions answered earlier. On the other hand, it might be wisest to wait until the Bill is finally passed before the question is put.

Some interesting things have happened recently. I listened to the broadcast a few nights ago by the Lord President of the Council, Mr. Herbert Morrison, when he gave an excellent address on democracy and the ambitions of the present Government. He said two things, however, which I am sure he could not have substantiated. He said that this Government was out for planning with liberty and order with freedom. That is just exactly where we ourselves stand, and if we look at the Lord President's speech concerning the Press a few days later we shall begin to wonder whether on the occasion of that broadcast he was not talking with his tongue in his cheek.

What is our position? The matter is entirely in our own hands. There are no other doctors but the doctors who are qualified. We are in the strongest possible position for ensuring that what we think is best for the public will be carried out. (Loud and long-sustained applause.)

ORDER OF ST. JOHN

The *London Gazette* has announced the following promotions in, and appointments to, the Venerable Order of the Hospital of St. John of Jerusalem:

As Knights: Major A. B. Cardew, M.C., Dr. T. H. Leggett. *As Commanders (Brothers):* Lieut.-Gen. T. O. Thompson, C.B., C.B.E., K.H.P., Lieut.-Col. R. W. M. Strain and C. G. Booker, Majors J. A. Mackenzie, and J. F. Hamilton, Drs. N. Jennings, N. Manson, W. P. Kennedy, and H. G. Ramsbottom. *As Commander (Sister):* Dr. Margaret E. Douglass. *As Officers (Brothers):* Col. T. D. Inch, C.B.E., M.C., Lieut.-Col. S. Le R. Spicer, Major P. Weiner, R.A.M.C., Capt. R. S. Harper, Surg. Lieut.-Col. H. R. L. Casolani, Col. J. Revans, M.B.E., and G. R. McRobert, C.I.E., I.M.S., Drs. N. S. B. Vinter, C. S. C. France, H. C. M. Williams, O.B.E., H. F. Hollis, K. E. Dowd, C. A. Gauthier, W. Bain, D. J. Nicol, M.C., T. W. A. Gray, S. H. Keshen, C. G. Roberts, L. A. Sigurdson, H. J. Porter, G. E. Dragan, and V. T. Camilleri. *As Officers (Sisters):* Drs. Gladys A. Danby, M.B.E., Gladys E. Wilkinsoo, Mary Rutledge, Daphne W. Dear, and Cecily Porter, and Miss Muriel J. L. Frazer. *As Associate Officer (Sister):* Major Barbara Stimson, R.A.M.C. *As Serving Brothers:* Col. A. C. Haddow, Lieut.-Col. E. J. Selby, O.B.E., Major A. K. Cosgrave, M.C., V.D., R.A.M.C., Majors J. Holmes, and R. A. P. Gray, Surg. Capt. C. C. Elliott, D.S.C., V.D., Drs. J. W. W. Baillie, G. N. Montgomery, T. M. Murphy, A. B. Davies, L. M. Maybury, W. Adams, G. E. P. Davis, G. E. Mullins, S. L. Smith, P. E. Malloch, V. S. Kaufman, W. A. Stos, E. R. G. Sheil, N. H. Skelton-Browne, F. N. Clark, D. Glen, J. M. Russell, H. S. Gabb, R. MacL. Thompson, E. M. Fingean, J. D. Gray, H. G. Parker, R. O. Davidson, B. M. Bennett, C. R. de C. Sadler, S. A. Hall, H. H. C. Fuller, J. C. Mead, G. K. MacNaughton, G. E. Kidd, W. R. Wright, J. G. Baldacchino, and G. C. Strathairn, and Messrs. K. G. W. Saunders, K. J. Gilchrist, T. J. Cobbe, and A. M. McMaster. *As Serving Sisters:* Drs. Ellen M. W. Shaw, Lilian I. McDonald, Teresa J. S. Iyer, M.B.E., Margaret M. Howe, and Lucretia H. H. Byrne.

Under the title of the Treacher Collins Prize Essay, the Council of the Ophthalmological Society of the United Kingdom has instituted a prize of £100, to be awarded triennially, for the best essay submitted upon a subject selected by the Council. The prize is open to qualified medical practitioners of any nationality, but the essay must be written in the English language. The subject for the next award is "Nutritional Eye Disease." The closing date for sending in essays for this award is Dec. 31, 1947. They should be submitted to the honorary secretary, Ophthalmological Society of the United Kingdom, 5, Racquet Court, Fleet Street, London, E.C.4, from whom also any further particulars can be obtained. No name should be on any essay, but a distinguishing pseudonym or quotation, which should also be upon a sealed envelope containing the candidate's name and address. This envelope should accompany the essay.

Nova et Vetera

EDINBURGH SURGEONS' HALL

The medical school at Surgeons' Hall, Edinburgh, traces its origin back to 1505 and may thus be said to be the oldest in Great Britain, but in its present form as the School of Medicine of the Royal Colleges of Surgeons and Physicians of Edinburgh it has now celebrated its fiftieth anniversary.

In 1839 James Syme, later Lister's father-in-law, urged that students should be allowed to take a certain number of terms at the extra-mural classes in qualifying for the Edinburgh University degree in medicine. The *Senatus Academicus* fought the idea but were finally overruled by the House of Lords in 1854. In 1884 the Privy Council was unsuccessfully petitioned to grant the extra-mural school a charter, and Miss Jex-Blake and her friends were on their toes to see that this would have compulsorily admitted women medical students; it was Dr. Peter D. Handyside who admitted women students to his anatomy lectures at Surgeons' Hall in 1870. However, an agreement was reached in 1895 between the extra-mural lecturers and the Royal Colleges setting up a governing body. This enabled the School of Medicine lecturers to receive and hold funds, which was important for the Carnegie Grants.

In 1913 an arrangement was made, further modified in 1917 and 1929, which fused the intra- and extra-mural clinical teaching, though many students at the university still take classes at Surgeons' Hall. More students at the school nowadays study for the triple qualification of the Scottish colleges.

The school's buildings in Nicolson Street are nearly 100 years old. A former student, who died in Australia, left some £50,000 towards the cost of a new building, but the war prevented its construction and the Goodenough Committee were thus able to make critical remarks about the accommodation, although no mention was made of the very excellent equipment in many of the departments.

Last year the school suffered a severe loss in the retirement of Dr. John Orr, lecturer since 1913 and Dean since 1924. His kindly character has left its imprint in the liberal atmosphere of the school, which causes many, particularly older people who are taking up medicine, to choose it. The present Dean is Mr. Norman Kemp, and Dr. Douglas Kerr has been appointed Director of Studies.

LAURENCE DOPSON.

DOCTORS IN THE LAW COURTS IN THE 13th AND 16th CENTURIES

Here is a rough translation of part of the Latin record on the *Curia Regis* Roll, Trinity Term, 14th year of King John (A.D. 1212), belonging to the County of Cornwall.

Osbert, the doctor, appealed Robert Bernard, who, he said, had spent the Sunday before mid-Lent with him, eating and drinking, and likewise the day after, on which day the said Robert sent to his wife that she should come to him on the following Monday. And on that said day his wife came together with his brother Thomas [who seems to have been in Holy Orders, as he is called *Clericus*] and two others and all these were with Osbert, eating and drinking, even unto the going down of the sun. And then Robert and the others nefariously and in the peace of the Lord King, took Gunnilda, Osbert's wife, and drew her out of the house and beat her with fists and knees so that they left her nearly dead; and then threw her over the hedge outside the orchard. They then took Osbert himself, drew him out of the house and beat him sorely. The assailants then entered the house and stole goods to the value of XX marks, including 11 gold rings, a silver-mounted cup, and a mazer likewise bound with silver. And this they did wickedly and in the King's peace, and Osbert offered to prove the robbery and the assault against Robert as the Court wished.

Robert, defending himself on the charges of breaking the King's peace, the robbery, felony and beatings, said that it was all a case of hatred and malice; that Osbert held a certain house of his for a term and that, as the term was up, he had entered into possession and made no robbery. He offered the King 3 marks that an inquisition might be held. And Osbert, asked whether he had raised the hue and cry, said that he had not, but had come to court to sue for his writ.

The result of the action does not seem to be recorded. One would suppose that Osbert and Gunnilda, after a day's debauch

and a good beating, would be in no condition to raise the hue and cry. As a tail-piece to this story the early Chancery Proceedings (1544-7) record an action brought by Richard We citizen and barber-surgeon of London, against Henry and Robert Savell, gents., Fellows of Lincoln's Inn, for enticing away 1 apprentice and for threatening to cut off his ears. High arbitrary folk they must have been, those Fellows of Lincoln's Inn. We are glad to think that the legal and surgical professions now located in that spot do not continue such evil practices.

The transcript of the Latin record was sent to me some years ago by my friend the late Mrs. Harvey Bloom.

R. R. J.

THE WOOLNER-DARWIN TUBERCLE

There are two busts of John Hunter in public places in London. The massive, romantic head by Alfred Gilbert, R.A. catches the eye from over the side-door of St. George's Hospital; but the bust in Leicester Square, where John Hunter had his town house, is less well known. It was carved by Thomas Woolner in 1874, the year that the square was opened to the public in which he was elected R.A. Sir Alfred Webb-Johnson later pointed out that this bust survived the Blitz only to be knocked about by hooligans, and that it ought to be restored; in the same speech he recalled Woolner's other claim to remembrance among medical men. Thomas Woolner had his first success in 1847 when he exhibited his statuette of Puck. It was admired by Tennyson and gained Woolner the friendship of Rossetti whom he joined in forming the Pre-Raphaelite Brotherhood for like Rossetti he was both poet and artist. But finding it impossible to make a living, he sailed for the Australian gold diggings in 1852; the farewell scene inspired Ford Madox Brown's famous and charming picture "The Last of England." In Australia he found portrait-sculpture more profitable than gold-mining, and came back to England two years later. He was a man of intellect and charm and moved in the most cultured society of mid-Victorian London. He set to work to portray the intellectual lions of the day. His bust of Tennyson established his name about 1857 and he later carved a head of Darwin. It was from him that Darwin heard of the tubercle of the auricle, one of the vestigial structures which became a clue in his argument for "the descent of man from pre-existing forms." The story is best told in Darwin's words:

"The celebrated sculptor Mr. Woolner," he wrote in the fifth chapter of *The Descent of Man*, 1871, page 22, "informs me of one little peculiarity in the external ear, which he has often observed both in men and women, and of which he perceived the full significance. His attention was first called to the subject whilst at work on his figure of Puck, to which he had given pointed ears. He was thus led to examine the ears of various monkeys, and subsequently more carefully those of man. The peculiarity consists in a little blunt point, projecting from the inwardly folded margin or helix. . . Now the meaning of these projections is not doubtful; but it may be thought that they offer too trifling a character to be worth notice. This thought, however, is as false as it is natural. Every character however slight must be the result of some definite cause, and if it occurs in many individuals, deserves consideration. It obviously consists of the extreme margin of the ear folded inwards; and this folding appears to be in some manner connected with the whole external ear being permanently pressed backward. In many monkeys which do not stand high in the order, as baboons and some species of macacus, the upper portion of the ear is slightly pointed and the margin is not at all folded inwards; but if the margin were thus to be folded, a slight point would necessarily project inwards and probably a little outwards. This could actually be observed in a specimen of the *Ateles beelzebuth* in the Zoological Gardens; and we may safely conclude that it is a similar structure—a vestige of formerly pointed ears—which occasionally reappears in man."

Darwin thus explicitly attributes the observation to Woolner but with the exception of Johnson Symington in his edition of *Quain's Anatomy*, who rightly refers to both Darwin and Woolner, almost all anatomists, English and foreign, call the structure "Darwin's tubercle," no doubt because he first described it in print. The Basle nomenclature termed *Tuberculum auriculæ Darwini*, but the Anatomical Society revised nomenclature of 1933 drops the eponym and calls it simply "tubercle of auricle." Symington reminds us that the tubercle is constant in the embryo of about the sixth month and occurred in about 30% of adult cases examined.

Reports of Societies

PENICILLIN INHALATIONS FOR LUNG INFECTIONS

At a meeting of the Section of Experimental Medicine and Therapeutics of the Royal Society of Medicine on July 11 the subject under discussion was penicillin inhalation for pulmonary infections.

Dr. J. H. HUMPHREY said that, like other workers, Dr. Joules had found that penicillin given intramuscularly was disappointing in the chronic cases, such as bronchiectasis and lung abscess, which made up a considerable proportion of the admissions to a county hospital. It was therefore decided to try some other method of approach. Patients willing to co-operate and presenting clinical examples of the various diseases were investigated. An estimation was made of the penicillin in their sputum. When penicillin had been given intramuscularly it could afterwards be detected in only 2 out of 26 samples of sputum from patients with chronic pulmonary disease.

Fortified by some American and other experience, they then gave penicillin by inhalation. Two types of inhaler were used, the Collison inhaler, which broke up the penicillin solution into very fine droplets, and the other the ordinary hand inhaler. Patients were asked to inhale, and afterwards—at intervals from two to eight or twelve hours—the sputum was examined. Relatively large concentrations of penicillin were found, and they were satisfied that this was a practicable method of administration. With the Collison inhaler it was found that a ten minutes' inhalation about 1.5 ml. of the solution could be nebulized. By giving four inhalations in the day, with a double dose at night, bacterial stasis was obtained over the twenty-four hours. Dr. Humphrey described the effect of inhaled penicillin on the various organisms. Diphtheroid bacilli and spirochaetes disappeared rapidly; others, such as staphylococci, *M. catarrhalis*, and occasionally fusiform bacilli, tended to persist. An examination of cases which came to necropsy showed that Gram-positive organisms persisted in the bronchioles long after they had disappeared from the sputum; therefore, even in the presence of negative sputum, treatment should be continued.

Clinical Indications

Dr. H. JOULES said that this treatment had been used extensively during the last nine months in the general wards. About 100 cases were treated by inhalation, and it had had a striking effect on the whole outlook of these patients in the winter and spring. The outstanding feature had been the elimination of coughing as a disturbing element in ward life. Previously the ward had "resembled a Cruft's dog show," but now serious coughing was confined mostly to patients with carcinoma of the lung and patients just beginning treatment. The general principle had been to give sulphonamide therapy at once when clinical examination showed pneumonic consolidation. When the initial examination suggested that it was mainly intra-bronchial aerosol penicillin was given from the outset. Sulphonamides had led to the rapid clearing up of the pneumonic process, but where there was a generalized bronchitis with some degree of spasm inhalation therapy had been of great value. It must not be supposed, however, that penicillin inhalation was the complete answer to the problem. Most Gram-negative organisms had resisted their efforts, and they awaited the coming of streptomycin or some such agent. Of 80 cases, all severe enough to be admitted to hospital, treated with penicillin inhalations, 46 had been much improved, 17 improved, and 17 not improved. Two cases of silicosis and bronchitis were not improved.

	Total Cases	Much Improved	Improved
Chronic bronchitis and spasm ..	20	15	5
Bronchiectasis ..	18	12	4
Respiratory infection with congenital heart failure ..	15	7	4
Pneumonia and generalized bronchitis ..	11	7	4
Lung abscess ..	5	3	0

He also related the experiences of a surgical colleague, Mr. L. Fatti, working at another hospital, who had used

penicillin inhalation in association with pneumonectomy and lobectomy. Without penicillin 13 cases out of 22 developed fistula; with penicillin in the pleural space, 5 out of 15 cases developed fistula, and with penicillin in the pleural space and inhalation, only 2 out of 18 cases developed fistula. The fistula rate in the three classes was thus 60, 33, and 11% respectively.

Dr. Joules spoke with some diffidence of the results of penicillin inhalation in cases of chronic tuberculosis with large amounts of sputum, but a considerable diminution in the amount of sputum had been obtained, and the patient's life had been made more comfortable. Penicillin inhalation had also been used pre-operatively for patients who had a tendency to bronchitis, but the series was too small and the bacteriological indications too indefinite to permit discussion as yet. On the whole, it was possible to give a guarded commendation of aerosol penicillin, but it was too soon to speak with confidence of the future lives of people with chronic pulmonary infections who had shown immediate improvement.

Dr. L. CAPPER said that experience at the London Chest Hospital confirmed Dr. Joules's remarks in general. A good deal of symptomatic improvement had been obtained with aerosol penicillin, but in many cases it was not the complete answer. He demonstrated a new penicillin inhaler which had been used at the London Chest Hospital for some months past. It was worked with an oxygen cylinder. Specimens of sputum collected on the following morning—some twelve hours after the last inhalation—had shown concentrations of penicillin reaching as high a level as 14 units per ml. The method had been used in suppurative pneumonitis, lung abscess, and carcinoma of the bronchus.

Dr. AVERY JONES asked whether any marked difference had been found in the results with the Collison and with the hand inhaler respectively. Dr. JOULES replied that the Collison had been used for the majority of the cases treated in the wards, whereas the other had been used for out-patients, and therefore no valid statistical comparison was possible.

ASSOCIATION OF UROLOGICAL SURGEONS

The British Association of Urological Surgeons met in London on June 27, 28, and 29. At the business meeting a memorandum on a urological service for the country was passed for submission to the Ministry of Health, through the Royal College of Surgeons. At the scientific session a discussion on "The Treatment of Benign Enlargement of the Prostate" was opened by the President, Mr. R. Ogier Ward, and continued throughout the morning. In the afternoon operations and demonstrations were given at seven London hospitals. A dinner, at which 82 members and guests were present, was held at the Royal College of Surgeons on the evening of June 28. The principal speaker was Sir Ernest Rock Carling, who complimented the Association on its memorandum putting urological requirements on a regional basis. It is proposed to hold the next annual meeting in Glasgow in 1947.

BIRMINGHAM UNITED HOSPITAL

In its eleventh annual report the Birmingham United Hospital, which includes the General Hospital founded in 1766 and the Queen Elizabeth Hospital at Edgbaston opened in 1938, welcomes back ten members of the medical staff after a long period of absence with the Forces, during which "they rendered most distinguished service in many parts of the world and achieved high rank and responsible office." Three members of the honorary staff have lately reached the retiring age—Prof. Seymour Barling, Prof. W. Gemmill, and Mr. Beatson Hird; and one other—Dr. R. H. Astbury—has retired for reasons of health; and the Board pays a high tribute to the services they have rendered. It has been decided to appoint to the staff three assistant physicians and five assistant surgeons, and in these appointments the new advisory committee, composed of the medical committee and representatives of the Medical Faculty of the University, is acting for the first time. The decision of Birmingham University to appoint full-time professors to the departments of medicine, surgery, midwifery and diseases of women, and paediatrics is welcomed. Much of the work of three of these professors will be carried out in the United Hospital. Financially the Board faces an uncertain future. Expenditure grows with new and extended services, and income shows no signs of expansion. "Devoted as the Board is to the voluntary principle . . . it must now be recognized that without some substantial increase in income the present full service given by the United Hospital cannot for long be continued."

Correspondence

Industrial Rehabilitation

SIR,—Further to the report of the B.M.A. Committee on Rehabilitation (*Supplement*, June 29, p. 187) you may be interested to have details of the industrial rehabilitation scheme now in operation at this factory.

A special rehabilitation machine shop or, as we prefer to call it, a Re-Training Shop, accommodating up to 40 persons, has been in operation here since April of this year. The shop is housed in a new building, and factors such as colour dynamics, lighting, and the local surrounding amenities have been the subject of special study. Here, through the medium of machine or bench work modified and adapted so as to secure the necessary movements, remedial exercises designed to assist recovery are prescribed for works accident and other cases under the direction of the company medical officer or the visiting orthopaedic surgeon. The shop is in charge of a whole-time rehabilitation superintendent, a trained engineer of some seniority within this organization and with an intimate knowledge of men and machines and of the many differing types of work done throughout this factory. Before taking up his duties the rehabilitation superintendent was given ample opportunity of studying the background of his work in its social, economic, and technical aspects. Working under the company medical officer, to whom he is responsible, his duties extend beyond the confines of the rehabilitation shop to fulfil what might fairly be described as those of an occupational therapist in the engineering sense with regard to placement of incapacitated persons within the factory generally. In this work he has the active co-operation of the personnel and employment managers. An assistant rehabilitation officer, selected on account of his personality and technical abilities as both teacher and demonstrator of machine shop practice in the apprentice school, is in immediate charge of the men working in the Re-Training Shop, and his services are available should the need arise for vocational training, for which provision is made within the framework of the scheme as a whole.

Although intended primarily for works accident cases, the rehabilitation shop also admits wounded ex-Service men and other employees injured while away from work if they are anxious to return, working in co-operation with the private doctor concerned and with outside hospital services and clinics. A considerable proportion of medical and psychological cases presenting difficulty in placement or as a result of prolonged absence from work constitute fully 50% of the cases dealt with, and the more difficult ones are admitted to the Re-Training Shop for graded work until such time as they can be satisfactorily accommodated elsewhere in the factory. In this connexion emphasis is placed on finding the "right job" rather than a "light job," and so far as aetiology is concerned our experience up to the present has tended to confirm the relative proportions of 25% surgical, 25% neurotic, and 50% medical cases mentioned in your leading article on rehabilitation on June 29.

While working in the Re-Training Shop the men are encouraged in a positive outlook towards recovery, and are directed to put a maximum effort short of fatigue into their work in return for a system of payment which is equivalent to their basic rates of pay plus 20% in lieu of bonus. Suitable work of a useful and productive nature is diverted from the factory and scheduled for the Re-Training Shop, and in comparison with production lines elsewhere in the factory where the group bonus system of payment is in operation efficiency rate is between 60 and 70%. In no sense is the Re-Training Shop regarded as a refuge for invalids, and the general morale of the men has remained consistently high. Since the shop was opened in April this year some 78 cases have passed through, of which 29% have been medical, 55% surgical, and 16% psychological.

Prejudice on the part of the injured workmen or lack of co-operation from others have been conspicuous by their absence, and it is becoming increasingly rare for accident patients to cease work while continuing under treatment at the factory or with the casualty or fracture clinic at the local hospital. In this respect the medical officer has the full co-operation of the private doctor. Plaster cases, if ambulant, are placed, wherever possible, at their usual work, or are found modified work within the factory, but failing this they are admitted to the Re-Training Shop.

The company medical officer works in close liaison with the casualty department and fracture clinic at the Luton and Dunstable Hospital, which is in charge of a full-time orthopaedic surgeon. Injured persons are asked to report back to the surgery on their return from hospital, and on the recommendation of the medical officer to the rehabilitation superintendent they are found suitable work wherever possible, thus maintaining continuity of treatment until recovery is complete. Ancillary to this service is a fully equipped physiotherapy department staffed by two whole-time mem-

bers of the Chartered Society of Physiotherapy, and here immediate treatment for works accident cases and after-treatment back to full work is provided for all those remaining at work. The orthopaedic surgeon attends the factory on one half-day a week and holds his follow-through clinic for injured and fracture cases in the physiotherapy department. The physiotherapist and rehabilitation superintendent attend this clinic as part of the rehabilitation team and accompany the visiting surgeon on his weekly round of the Re-Training Shop.

Cases requiring further investigation or x-ray examination or plaster changes at the fracture clinic, which is held in the local hospital, are collected together at the end of the week and, in company with the rehabilitation superintendent and the physiotherapist, are transported to and from hospital by coach at the company's expense. In this way close co-operation between surgeon and engineer is thereby secured and has a marked effect from the psychological point of view on all those undergoing treatment. It also has the advantage of saving much time and trouble which might otherwise have to be spent in an already overloaded outpatient department. A consulting plastic surgeon is also a member of the rehabilitation team and sees cases both at the hospital and in the factory in consultation with the orthopaedic surgeon and the company medical officer.

Some form of rehabilitation has long been practised at this factory where people injured at work or returning after prolonged illness have received special consideration on the recommendation of the medical officer through the active co-operation of foremen, managers, and the personnel department. This co-operation is none the less evident with the establishment of a comprehensive rehabilitation scheme, and I look forward with confidence to an ever-widening field for this very important advance in social medicine.

—I am, etc.,

A. R. THOMPSON,
Medical Officer.

Vauxhall Motors Ltd., Luton.

Drug Eruption after Sodium Pentothal

SIR,—With reference to drug eruptions due to sodium pentothal, mentioned by Dr. G. A. Grant Peterkin (July 13, p. 52), the following case report may be of interest.

Mr. H., aged 40, was admitted to this hospital under the care of Mr. W. Donald Bedford for a radical cure for bilateral inguinal hernia. The operation was carried out under pentothal and nitrous oxide. Thirty-six hours after operation an urticarial rash appeared on the patient's chest, face, and arms and a scarlatiniform rash on his hands. Post-operatively the patient had only had glucose drinks and some luminal. The luminal he had had before operation without any reaction, and it was supposed that this rash was due to the pentothal.

The urticaria settled down with calcium lactate injections, and five days after the appearance of the rash his hands started to peel. As in the case reported by Dr. Grant Peterkin, a patch test for pentothal was negative.—I am, etc.,

Hertford County Hospital.

M. D. WARREN.

SIR,—In his medical memorandum on "Post-operative Mania treated by Continuous Intravenous Pentothal" (June 22, p. 954), Dr. A. Robertson Kerr makes the remarkable statement that "little has been written about the action and effects of sodium pentothal, even as a short-acting anaesthetic."

R. Charles Adams, in his book *Intravenous Anaesthesia*, quotes 260 references in the chapter on pentothal, and, of course, there are many more publications which either were not referred to in the text, or have been published since the book went to press in 1944.—I am, etc.,

Accra.

G. M. WYANT.

Amnesia after Trilene

SIR,—Towards the end of "A short Survey of Trilene in General Practice" (July 6, p. 10), Drs. A. Barratt and S. H. B. Platts state that "An interesting and otherwise unencountered property of trilene has come to light. In rather more than 20% of cases complete amnesia followed its use." The italics are mine. They suggest that this figure might be raised by certain expedients. I notice that their bibliography does not refer to my article "Trichlorethylene and Midwifery" (*J. Obstet. and Gynaec. Brit. Emp.*, April, 1944), in which the following appears: "All patients were amnesic. Some had short retrograde amnesia and were bewildered at finding delivery completed, having no recollection of the application of the mask."

Incidentally, Drs. Barratt and Platts might find that the use of the simple cheap apparatus described by me would raise

r 20%. I hope to make a further communication regarding suitability of this apparatus for general practice midwifery in early date.—I am, etc.,
ackport.

WALTER CALVERT.

Statistics and Mathematics

SIR,—If Mr. P. J. Hilton and Dr. S. M. Hilton (July 20, 1946) used fewer technical terms and paid more attention to ordinary usage of words, they would be better equipped to instruct your "non-mathematical readers," among whom I hesitatingly rank myself. When your correspondents have a little more experience, they will realize that something more than a facility in the use of arithmetic and algebra is needed to justify the title of mathematician.

Dr. Rewell was confronted by an "event" which, on the hypothesis of "chance," would be a statistical rarity; he therefore entertained an alternative hypothesis. I have but a superficial knowledge of genetics and am humble-minded enough to believe that he was justified in reporting his observation so that statisticians might consider the alternative. Your correspondents attempt to show that Dr. Rewell claimed that *he* had statistically demonstrated the superiority of the alternative hypothesis. Is this done by italicizing the word "must" in a particular instance. We all use words in common speech a little loosely, as in your correspondents. They were not "constrained"—i.e., forced—to ask anybody any question; still less to apply wholly irrelevant extract from a paper of mine in a disparaging sense to Dr. Rewell.

I should think a "real" mathematician might connect two uses of algebra with the words, "We must conclude"; and might say to his wife at breakfast, "My dear, I must catch the 9.30 train"; and that the same word would be understood by any man to have a slightly different connotation in the two cases. Had I said in my letter, "I am afraid Mr. Hilton and Dr. Hilton are talking dreadful nonsense," I think they would have been wholly justified in accusing me of discourtesy. If they had said: (a) that I clearly did not understand what fear is and quoted an article on claustrophobia; (b) that nonsense, however irritating, simply could not excite dread; I, and your other readers, would have thought them merely silly.

The application of statistical methods to medical investigations has been the business and pleasure of my life for nearly 30 years and will continue to be its solace. I can remember with scornful contempt with which many of the leaders of our profession treated that sort of "mathematical trifling" long ago and rejoice in the change of attitude. Your correspondents perhaps underestimate the proportion of your readers who are familiar with the technique of biostatistics as they are. But agree that many of your readers are bored by technical jargon. Then, they find the author of what seems to them a modest and sensible annotation rudely pelted with jargon, they will not form a pleasant idea of the use of statistical methods or of the manners of statisticians.

That, Sir, is why I, rather officiously, defended a colleague who may well have thought he needed no defence.—I am, etc.,

MAJOR GREENWOOD.

Book Reviewing

SIR,—I was delighted to read Mr. H. Osmond Clarke's plea for signed reviews in your issue of July 20. The uninstructed may come fresh to the reading of a weekly medical journal might well imagine that half the paper is written by two or three industrious and omniscient gentlemen, sitting in an office and vigorously scribbling from Thursday morning to Tuesday night. Even the less ignorant would be surprised if they were made aware of the number and distinction of your anonymous contributors. The modern trend in journalism is rightly in favour of publicity; one of the last redoubts of anonymity to fall was the *Punch* book reviews, which are now signed by the initials of the writer, whose full name is later given in the index. It is possible that book reviews might be kinder to the authors if this practice was adopted in medical journals, though no one could accuse medical reviewers of consistent harshness or unfairness. Indeed, it would be as easy to make a case against them for excessive generosity.

It might be argued that literary reviewers have grown in charity as they have discarded their anonymity, but this decrease

in bookish ferocity is related rather to the increasing mildness of public manners in the last hundred years, particularly since the twentieth century has provided us with other outlets for our aggressive instincts. I have not observed that present-day reviewers lack the courage to state their opinions forcibly. I can recall a review of Rebecca West's which runs thus in my memory: "Mr. X.Y.Z. has written another novel. How long, O Lord, how long?" And the book of a distinguished lady novelist, entitled *This is the End*, which earned the laconic tribute from a literary knight that he hoped it was. From what I know of your modest contributors I should say that their reputations are sufficient to sustain their opinions, and their characters firm enough to defend them.

Away, then, Sir, with anonymity.—I am, etc.,

Derby.

DOUGLAS HUBBLE.

SIR,—Although, as an author. I have had nothing but most helpful criticism from your reviewers, I should like to support Mr. H. Osmond Clarke (July 20, p. 102) in his request that the reviews should be signed. A signed review carries authority, and is far more interesting to all readers than an anonymous review.

While on the subject of the review column, I have gained the impression that as much, or even more, space in your *Journal* is devoted to reviews of foreign books as of those emanating from the British Empire. Many of these foreign books are on subjects of little interest to the general reader, and on several occasions lately I have found that foreign surgical books that you have reviewed are unobtainable through the leading London medical libraries. I suggest that, if I am correct (and no doubt someone can be found to supply the statistical data), it would be a good rule to devote two-thirds of the available space to reviews of British books, and relegate some of the foreign works, particularly those on extremely specialized subjects, to the "Notes on Books" section.—I am, etc.,

London, W.1.

HAMILTON BAILEY.

SIR,—I was very interested to read the most instructive letter (July 20, p. 102) written by Mr. H. Osmond Clarke dealing with the subject of reviewing medical books. I would like to draw your readers' attention to another aspect.

I have carefully analysed all reviews since August 4, 1945, to the present date, July 20, 1946. In these fifty-one issues I have tabulated all reviews published. Pride of place always seems to go to the American publications, and on 26 occasions an American book has been given the first place under "Reviews" in your *Journal*. British books fall short with 22, while foreign publishers have had this honour on three occasions. Why over-emphasize American books and relegate British books to an inferior position?

Further, when an important new edition is published by British publishers the review is often relegated to the last section of reviews under "Notes on Books," and very often a most important book is dismissed in a few sentences, while anything that comes from either American or foreign sources, is given undue prominence. Should we encourage this inferiority complex or are British books deteriorating that we are afraid to give them the publicity they deserve? Is it not time that we started to sponsor our own wares, or at least see that British books are given a square deal and the brake put on in trying to flatter these American tomes?—I am, etc.,

Edinburgh.

E. A. McWHIRTER.

Paralytic Ileus

SIR,—While looking over some old copies of the *Journal* on my return to civilian life after four and a half years' service, I noticed in the correspondence columns (Feb., 1946) a discussion on post-operative ileus. In the methods suggested for the amelioration and prevention of this distressing complication I could find no mention of physiotherapy as a possible means of relief and prevention.

For reasons not far to seek, physiotherapy has never really been allowed its proper place in this country as a definite department in the practice of medicine and surgery. There has always appeared to be a tendency for the average practitioner to regard physiotherapy as the province of the "medical electrician" and the masseuse. In most hospitals I have been in, in England, the physiotherapeutic department is relegated

to the basement of the building in what, under other circumstances, would have been the cellars. This department, as a rule, has no specialized chief-of-staff, but is under the *aegis* of the radiologist, dermatologist, or orthopaedic surgeon, none of whom would appear to place much faith in this cuckoo in the nest. Prior to the war there appeared to be a tendency to relegate the so-called hospital chronics to this department as a sort of last resource, on the principle that if it did not do them any good it could not do them any harm. The illusion that the beneficial results of physiotherapy are solely of a psychological nature appears to be still present in many minds.

In America, however, physiotherapy has long since found its place in the armamentarium of the physician and surgeon. Post-operative, short-wave, infra-red irradiation of incisions in abdominal and pelvic surgery have proved of inestimable value, speedily banishing pain and promoting rapid healing. Miller (*Arch. phys. Ther.*, 1932, 13, 99) subjected cases, forty-eight hours after operation, to a 30-minute exposure, the point of intensity of I.R. being focused on the abdominal wound, which was denuded of dressings. This irradiation was followed by a general U.V. treatment administered to the body sectionally. He described the effect of I.R. on the tense, distended, and tender abdomen as spectacular. Patients who were writhing with pain went off to sleep before the 30-minute treatment had been completed. His splendid results with post-operative ileus convinced him that, if I.R. could relieve, it would prevent this, and his experience goes to prove that it does. The effect produced by I.R. on the static post-operative intestine is, at least in part, explained by its penetration, the production of heat in the tissues, and the dilatation of the blood vessels, bringing a greatly increased supply of fresh arterial blood to the part. Miller thought that it might further be explained on the basis of reflex action. The nerves arising from the spinal cord supplying the abdominal skin have also sympathetic branches which supply the abdominal viscera. Inflammatory conditions within the abdomen cause increased sensitivity to corresponding skin areas. Miller's contention was that the soothing action of the I.R. rays upon the nerves supplying the abdominal skin reflexly caused a relaxation of tension within the abdomen through the spinal sympathetic innervations. He admitted that this theory was, of course, speculative, but he believed it explained the action of I.R. upon the static bowel.

Another aspect of abdomino-pelvic operative cases subjected to routine post-operative I.R. therapy was that they very seldom had the common complication of retention of urine. Miller found, on comparing records, that those abdominal cases treated as described not only had relief from the greater part of the usual post-operative distress, but that they rested better, healed more quickly, gained strength more rapidly, and, as a consequence, spent approximately $3\frac{1}{2}$ days less in hospital than those cases not so treated.—I am, etc.,

London.

R. DOUGLAS HOWAT.

Rheumatic Fever

SIR,—In view of the opportunities for the study of rheumatic fever in the American and British Armed Forces, Dr. H. S. Barber's paper on "Rheumatic Fever in the R.A.F." (July 20, 1946) is of considerable interest. Unfortunately, as in so many other medical publications, the literature of the subject has been most superficially reviewed and quoted, but possible observations on the clinical condition of the patients is minimal, and various lines of investigation seem to have been left unexplored. It is very difficult to understand how rheumatic joints can be considered an allergic manifestation; as Dr. Barber obviously inclines to this belief, will he explain the response of the joints, the fever, the sweating, and the pain, to sodium salicylate, and does he regard the peculiar distinctive rheumatic pathology (the Aschoff body) as an allergic manifestation?

If this belief of allergy of rheumatic manifestations can advance our knowledge of rheumatism, either its aetiology or its treatment, I shall be content, but if the supposition does not help in diagnosis, prognosis, or treatment, why use the term? It seems to be suggested in this paper that the joint manifestations in poliomyelitis or tuberculosis are allergic; I suppose that Dr. Barber knows of the joint changes which occur after hemiplegia? Is this also an allergic manifestation? And what is the explanation of the fact that such joints do not respond to treatment with sodium salicylate?

This paper is disappointing in that there is no detailed account of treatment. There is no mention of E.S.R. rates and how these changed as convalescence went on. Nor are we given any information as to x-ray changes, although we are told that when there was a doubt the size and configuration of the heart were checked radiographically. How exciting it would be if any of those expected concertina-like expansions and contractions of the heart were actually encountered and recorded.

Acute rheumatism is a very difficult subject; many years of the closest possible observation with the best possible clinical investigation are essential, and papers which merely quote literature and mention a small number of cases will not advance knowledge.—I am, etc.,

Birmingham.

K. DOUGLAS WILKINSON.

Shock Treatment of Bronchial Asthma

SIR,—Bronchial asthma, like other allergic conditions, can be considered as an expression of parasympathetic irritation. In terms of immunology it is like anaphylaxis, a state short of immunity. Anaphylactic shock in experimental pathology may lead to complete immunity—if the animal survives. Similarly, shock in an allergic person may lead to longer or shorter immunity—if doctor and patient are prepared to take the risk involved. I had the good fortune not to have a fatality among the great number of allergic patients treated so far. Other specialists have been less fortunate. I remember, however, with some trepidation two very severe shock reactions observed by me in the early twenties when methods were less elaborate. One, a boy who developed lung oedema, fall of B.P., and collapse after injection of antitoxic diphtheria serum (an atopic type of allergy); the other, a young woman with hay-asthma and similar signs of shock after a strong injection of pollen extract.

Since then I have had, and still have, the opportunity to see a very great number of asthma patients, both in hospitals and in private practice. I think that everybody with similar experience will agree with me that the variety of causes leading to asthma is great, and of varying importance not only in different patients but also in the same individual at different periods of his life. By long experience I have come to the conclusion that by far the best results are obtained by a complete analysis of all relevant factors through a careful case history and complete investigation of each case, including allergic skin tests or other allergic tests.

Apart from the symptomatic treatment of the attack by stimulation of the sympathetic nervous system (adrenaline, etc.) or paralyzing of the parasympathetic (atropine, etc.), full immunization or lowering of the irritability of the parasympathetic is the aim, and may be obtained by specific or unspecific desensitization, ranging from a mild shock therapy by injection of the patient's own blood to a prolonged or quick desensitization with the specific allergens (hay-asthma). The doctor who deals with these conditions should always be aware of the dangers involved. He should also be aware of the fact that so far there is no royal road leading to success in all asthma cases. There is, however, hope that this may be achieved by intensified research in the not too distant future, and I can think of a number of ways which may ultimately lead to full understanding and full success.—I am, etc.,

London. W.1.

E. M. FRAENKEL.

The Hypochondriac's Treatment

SIR,—Dr. E. D. Granger (July 6, p. 27) has given his interpretation of Dr. Summerskill's phrase "in future no doctor need prostitute his service by pandering to hypochondriacs." May I be permitted to give mine?

The treatment of moderate degrees of neurosis should constitute an important part of the G.P.'s work—a part which could be of tremendous service to the patient, his relatives, and the community. He has intimate knowledge of the patient's emotional, domestic, and financial background, and this should enable him to advise the latter how to make the most of his life. Yet all too often this side of general practice is partially or wholly neglected. Why?

A.—In the case of the *neurotic private patient*, the reason is summed up in the words of the old doctor who said to his young

1 enthusiastic assistant: "For goodness' sake don't cure that man. I'm relying on her to educate my son." Few doctors will t their whole heart into the treatment of a patient when they ow that a successful result will mean a large slice off their income. 3.—The *panel neurotic*. Treatment of neurotics takes time and ience. Will a doctor spend an hour talking to a panel neurotic the morning surgery when he might be doing half a dozen rivate" visits? Some doctors may, but many will be tempted send him off with a "bottle of medicine" and a "neurasthenia ificate." (Panel patients who are coal merchants, grocers, or ultry-keepers come, of course, under class A. They are the *me de la crème* of any practice.)

How I should like to see an inquiry into some of these pink neurasthenia certificates"! No doubt there are many cases anxiety neurosis, due in part to overwork, which do respond a few weeks' rest. But there are a large number of other pes of neuroses for which the cure should be rehabilitation suitable work. In this type of case the best doctor is the ie who has the moral courage to refuse the pink certificate. Under a National Health Service, where one patient does not ffer in financial value from another, there should be no incen-re to postpone the cure of the private neurotic. Doctors can eerfully spend the necessary time on panel neurotics in the cure knowledge that the Government is looking after their ancial interests.—I am, etc.,

Rotherham.

ANNE M. TOMS.

Penicillin and Venereal Disease

SIR,—I have read with interest recent letters on the above bject and would like to add mention of a case of gonorrhoea rticularly resistant to penicillin.

The patient, a male aged 25 years, was admitted to hospital with purulent discharge of twenty-four hours' duration, and on micro-opical examination a diagnosis of gonorrhoea was established. A urse of three injections of 50,000 units of penicillin every four urs was given with a reduced fluid intake, and the discharge dis-appeared. However, forty-eight hours later it reappeared with no story of re-infection. A further similar course was administered id again the discharge disappeared, and a rectal examination owed no evidence of prostatic infection. The patient seemed uite fit and was discharged.

One week later the patient returned with a generalized papular ruption, joint pains, temp. 103° F. (39.4° C.), pulse 90, and marked alaise. A prostatic examination revealed a tender swollen area of ie upper pole of the left prostatic lobe; the seminal vesicles peared normal. The rash lasted only twenty-four hours and was garded as allergic, but the left wrist-joint, the proximal joint of ie right great toe, and the left sternoclavicular-joint became the at of an acute arthritis. It is interesting to note that though the ernoclavicular-joints are only affected in 2% of gonococcal arthritis, is very rare for these joints to be involved in any other form of rthritis. Again penicillin was administered and 250,000 units were ven in all. Frequent prostatic massage and pot. permang. irriga-ons were commenced. In three days the arthritis subsided and the lammation of the skin overlying the joints disappeared. After a urther two days the prostatic swelling and tenderness were abseni nd the urine remained clear in all three glasses. Blood taken at ie commencement of the arthritis gave a positive serological result.

I feel that this and many other cases I have had of recurrent ischarge, after the usually recommended total dose of 150,000 nits of penicillin, indicate that this amount may be inadequate nd perhaps ought to be as high as 250,000 units per course as dvocated in America.—I am, etc.,

L. GRANT DUFF,
R.A.F.V.R.

Istre.

Notification of Venereal Disease

SIR,—I was recently serving with about six hundred Royal arines in the vicinity of Newcastle, N.S.W., a large industrial own and the centre of the Australian steel trade. Over a eriod of six months I had no cases of venereal disease, except ne or two cases of gonorrhoea acquired by men on passage ut from the United Kingdom. The medical officer in charge f the Newcastle Hospital told me that he had only seen three rimary chancres in the past ten years, and that gonorrhoea was ractically non-existent in the town.

This condition had been achieved by compulsory treatment, nd penalties if the patient defaulted. He informed me that the enalties were never enforced, but were a useful threat. I feel hat if such a desirable state can be obtained by compulsory eatment there is no possible excuse for allowing our present ax methods to continue. It would be a very strange man,

whether he was a venerable dean or a bus conductor, who has not at some time or other run the risk of venereal infection, and I think it is about time the obvious course was taken with these diseases.—I am, etc.,

Fareham.

G. G. THYNE.

Psychology in the Child's Education

SIR,—Dr. D. W. Winnicott (June 29, p. 998) recommends regular visiting to ensure that small children in hospital retain their emotional contacts with their parents, which means in some measure, to use Dr. Winnicott's provocative phrase, "keeping them sad." Dr. J. A. McCluskie (July 13, p. 62) hazards that it is the initial separation that does the damage and advises against its repetition by frequent parental visits.

It is obvious that an issue of this kind will not be solved except through properly planned research, and Dr. McCluskie's call for controls is timely. Yet the evidence, such as it is, is very much against his view. The cases which I personally have seen have been of children who, between the ages of 1 and 5 years, have been in hospital for many months *unvisited*. Their most striking symptom has been habitual stealing, and their most important feature, psychopathologically, an impaired ability to make emotional relations with their parents and others. I have seen no child in the same mental condition who had spent the same number of months in hospital during these years and who had been regularly visited, though I have seen many in this condition who have had an experience similar to being in hospital *unvisited*—e.g., temporary placement in institutions or with foster-parents. The association between long separations in early childhood and later incapacity to form good personal relationships can be demonstrated both statistically and clinically.

Workers who had experience with children in residential nurseries during the war agree that the children who were easiest to manage were those who had good home ties and could look forward to regular visits. Those who became difficult were those whose mothers rarely or never visited and who felt, in consequence, deserted. They became either extremely demanding of the attention and affection of members of the staff or else apathetic. Many such children are now being referred to child guidance clinics in the London area for difficult behaviour and stealing.

I believe that an adequate survey would demonstrate unmis-takably that a proportion of children who are separated from their mothers for long periods in early childhood suffer some mental damage, much of which could be prevented by a system of regular weekly visits. That some children do not suffer in such circumstances is also highly probable. How big the proportions are and what other factors are operative remain problems for further research.—I am, etc.,

The Tavistock Clinic, London, W.1.

JOHN BOWLBY.

SIR,—It is regrettable that Dr. D. W. Winnicott (June 29, p. 998) should impute that the main suggestion in my letter (June 15, p. 930) is "to the effect that children should be taught as the Nazi children were taught, only taught citizenship." I only referred to the readiness with which children were indoctrinated with principles of racial superiority in order to indicate how responsive they are to any method of teaching. The emphasis was on *their responsiveness to teaching* and not on teaching by means of a totalitarian system, which clearly could only produce precocious and undesirable conditioned reflexes.

A satisfactory scheme for the education of children in their instinctive and emotional reactions would have to be worked out by educational experts, bearing in mind, as Dr. Stephen Krauss (June 29, p. 998) so rightly emphasizes, the various phases in the normal development of the child. In order to obtain satisfactory results, greater attention would have to be paid to emotional development and intellectual capacity than to age in the segregation of children into classes.

I entirely agree with Dr. Winnicott that "the real source of good citizenship is in the life of the child in his own home"—provided that the parents are stable, happy, and intelligent. Unfortunately, a substantial proportion of parents are just as unsuitable for their job as are many teachers. We cannot select parents as readily as we can choose teachers, and I accordingly suggested that psychological guidance should be initiated at school. By all means let us learn as much as we can from

children, as Dr. Winnicott suggests, which is tantamount to saying that we should learn all we can about instinctive behaviour and human nature. My plea is to guide children along such lines, but there is no reason why adults should not also be encouraged to accept guidance and training in psychology. Dr. Winnicott asks, "Why is it that when we start planning we so easily start on the wrong foot?" I suggest that it is better to start on the wrong foot than never to start walking at all. But are we starting on the wrong foot? Are not children the parents of to-morrow, and by instituting psychological guidance in schools would we not, in fact, be rendering future parents more suitable for their jobs, so that the chances of subsequent generations starting off on the right foot in the direction of good citizenship would be all the greater?

I cannot appreciate Dr. Michael Fordham's objection (July 13, p. 62) to doctors expressing their views regarding the school curriculum. He would like us to leave teachers to their own job. My letter does not suggest depriving them of their function. Doctors, with their greater opportunities of getting to know and understand people, are in a good position to suggest what is good for them. My plan to introduce psychology into the school curriculum surely cannot be regarded as a medical encroachment on the teacher's province. Dr. Fordham would appear to support the idea of careful selection of teachers in so far as he agrees that "it is useless to talk on the subject of behaviour unless they themselves are good citizens," and for some reason or other he has decided that "if they are good citizens it is only of secondary importance what they say to children."

It is not sufficient, in my opinion, for teachers to have stability, character, intelligence, aptitude, freedom from prejudices and rigid social, political, or religious attitudes. They must know what to say, when and how to say it. It is not the doctor's business to teach teachers, as Dr. Fordham stresses, but surely we can all make suggestions, pool our knowledge, learn from each other, plan for the future, and endeavour in every possible way to make the world a better place to live in.—I am, etc.,

London, W.1.

ELLIS STUNGO.

Socialism and the Pay-bed

SIR,—It is surprising that no one has so far replied to the points raised in the letter from Mr. J. B. Macalpine (June 22, p. 968). The insult to ordinary hospital patients implied in the view that large numbers of them are unfit for civilized company hardly needs an answer; but one hopes that no doctors really feel such contempt for these people. Incidentally, in my experience nurses who have worked in private wards have not always found their occupants to have that uniform selflessness and exquisite sensibility which Mr. Macalpine appears to associate with the ability to pay for separate accommodation.

The latter parts of the letter are not quite clear, but I am not aware of any evidence to support the view apparently held that the higher income groups have a superior genetic endowment. The highly coloured tone of these arguments hardly ports the claim made for our profession to act as biological vectors to the community.—I am, etc.,

S. S. ALEXANDER.

The Health Service Bill

SIR,—I was heartened to read Dr. Victor Russell's lucid letter (June 1, p. 846), as he says if the Government were genuinely desirous of improving the medical services, some well-tryed scheme on the lines of that used in New Zealand would be effective, without raising the issue of nationalization with all its associated administrative problems.

If this is applied, there is a free service in *all* branches of medicine for *all*; further, hospitals can retain their present status, but as every patient is a paying patient they need no longer be dependent on charity. Obviously, the better hospitals would be more popular, and a spirit of competition in providing the best hospital service would result; if the Government chose to build its own hospitals as well, this would provide added stimulus, and it would be interesting to see which proved to be the better of the two. If a sound counter-proposal like this could be presented to the lay public in simple language by the *B.M.J.* we should be in a position to reject the present dictated terms of the Minister *in toto*.

It is interesting that some months ago I was asked to address a meeting of airmen (almost all Socialist) on the Bill. At the end I was asked if the profession had any alternative to offer I had to admit that they had not, but described the outlines of the New Zealand scheme. At the end I asked the chairman to take a vote, just as a matter of curiosity, and over 90% were in favour of some such scheme being adopted in lieu of the present measures. Why has this scheme never been really publicized? Is it too simple for politicians to grasp? I have met a number of New Zealand laymen in the Forces, who say it works excellently.—I am, etc.,

Cyprus.

J. H. BERGIN,
Flight-Lieut. R.A.F.

Authority and Independent Thought

SIR,—In his Price Lecture on epilepsy (July 6, p. 1), Dr. Gordon Holmes deals with this disease in his usual masterly fashion. He traces the theories of its aetiology from the time of Hippocrates up to the present day, passing on the way through a period in our history which saw the foundation of Eton and Winchester, Oxford and Cambridge, and scores of universities on the Continent of Europe, and which, as an eminent churchman recently said, "we of the atomic age still have the impertinence to miscall the Dark Ages." Throughout this lecture there is a recurring thought that seems to dominate the whole picture—i.e., the idea of conflict between authority and independent thought. If by "authority" Dr. Holmes means the authority of the text-book which sets forth masses of facts copied from other books (and errors as well), assigning rarely, if ever, a reason to account for any fact, then one must agree that the student who contents himself with absorbing such information is certainly not stimulated to independent thinking. So, too, in days gone by, even in the "Not-so-dark Ages," those who slavishly followed the current superstitions whether they concerned the fermenting humours flowing in the blood stream or the supposedly malign deeds of "witches," and forbore to use their critical faculties did grave disservice to their fellow men. But let us not forget that the mere 100,000 "witches" burnt in Germany fade into insignificance beside the extermination of millions of Jews in the same country in this age of enlightenment.

Dr. Gordon Holmes apparently subscribes to the view that the Church has been the enemy of science, a view that is no so widely held as heretofore. If so, why did the Church found universities? They were bound to stimulate independent thought. The Church, it is true, will only accept incontrovertible facts as truth, and has always refrained from acclaiming new theories with uncritical enthusiasm. This has often led to misunderstanding and, inevitably, also to misrepresentation. "Science which brings man nearer to God," to use Pasteur's phrase, can never be in contradiction with the Christian faith. It was Pasteur also who said, "I see everywhere the inevitable expression of the Infinite in the world." Dr. Holmes is a renowned authority on the subject of nervous diseases, an authority that we all bow to, but when he forsakes this sphere and ventures out into the realms of "dogma" and "heresy," etc., he is much more vulnerable.—I am, etc.,

Belfast.

E. M. HICKEY.

Nutrition of Far East Internees

SIR,—In the report of the Nutritional Society's Conference (July 6, p. 22) I was interested to read Dr. Cicely Williams' reference to nocturnal diuresis amongst the Far East internees. Last year I met many internees in Hong Kong and Shanghai and this subject was always prominent in their impressions of internment life. I have seen no explanation in the *Journal*. The internees attributed the diuresis to rice. Subsequent observation of the Japanese seemed to substantiate this. During three and a half months in Japan I cannot remember going more than a few hundred yards without seeing someone micaturating in public. Is the urge behind this national characteristic attributable to their rice diet? If so, is it the water content or a specific diuretic? Perhaps some able mathematician will work out the number of people to be observed micaturating per mile in this country if such was the custom, and so confound the observation! The persistence of diuresis for a few weeks after liberation may be explained either by habit or, as in so many cases, continuing with rice.—I am, etc.,

Worcester.

C. ROMER.

Medical Notes in Parliament

HEALTH SERVICE BILL

REPORT STAGE—SECOND DAY

When the Debate was resumed on July 23, Mr. HOUSE moved amendment to Clause 33. He proposed to insert the words "others" after the words "medical practitioners" in the section that every Executive Council shall make as respects area arrangements with medical practitioners for the provision of personal medical services for all persons who wish to advantage of the arrangement. He said that nature-cure practitioners who reached a required standard of training and qualification should be recognized under the Bill. Such practitioners comprised naturopaths, osteopaths, and others. Patients should have the free and unfettered right to attend the practitioner of their own choice. Medical practice so far as it was based upon the application of medicines, drugs, and vaccines was undesirable. Mr. HOUSE referred to Mr. BEVAN's recent speech, and remarked that in consequence of it he had lost a week or more of the Committee stage of the Bill. He said he had seen Mr. BEVAN since with his little tins and pills and leets. There had been an inquiry into osteopathy by the use of Commons in 1935, but the inquiry board was committed to a large extent of medical representatives, and so was fair to start with. Furthermore, the osteopaths were not tidy and many of their witnesses conducted their case dishonestly.

Sir ERNEST GRAHAM-LITTLE said there had been a second inquiry in the House of Lords by a Select Committee. This was a very large number of sessions. In the middle of that inquiry the osteopaths threw in their hand and said they were not going further. Mr. EWART seconded the amendment and asserted that workers would not get the benefits of physiotherapy.

OSTEOPATHY AND ORTHODOXY

Mr. BEVAN said he thought that the heterodoxy of yesterday came the orthodoxy of to-day, and that the medical profession to-day practised many forms of therapy which it yesterday rejected. He did not intend to commit the indiscretion of forming a judgement on the relative merits of one form of therapy against another. The House was discussing an amendment which would place on the Executive Council in each area the obligation of providing whatever kind of medical attention any citizen might want. That was an impossible suggestion. The consequence would be that any policeman, Dick, or Harry would be able to prey upon the credulity of any citizen and could call upon the State to provide the money for that service. It was true that under the National Health Insurance Acts there was some provision, rarely exercised, for the subvention of a person who wished to have some form of medical treatment. That was difficult to administer, and if it were extended would be impossible to administer. Physiotherapy and occupational therapy were being extended and had been fostered by distinguished doctors.

Sir HENRY MORRIS-JONES said fine cures were achieved by nature-curers and osteopaths, but their failures were unknown and unsung. In many cases such treatments delayed orthodox treatment and resulted in a great loss of lives.

Sir ERNEST GRAHAM-LITTLE said that twenty years ago he had asked the House to institute an inquiry into the whole question of irregular practice. That inquiry was very necessary. Schools of naturopathy in this country were few and ill-equipped, and examinations were just puerile. Osteopathic schools were entirely confined to America. Sir Ernest recalled that Mr. Neville Chamberlain, then the Minister of Health, said he could not recognize examinations carried out in another country, and that when the osteopaths decided to follow courses of study approved as suitable for medical practice in this country there would be no difficulty in getting them recognized. Until an established scientific inquiry had been instituted there should be no recognition of any section of irregular practice. At present, quite properly, the irregular practitioner was not recognized. The amendment proposed by Mr. HOUSE was negatived.

Mr. TURTON moved an amendment dealing with the issue of medical certificates. Mr. BEVAN said that at present the issue of certificates was limited to those connected with insurance work. The Bill extended this. Further certificates would be issued for the purpose of any enactment under which certificates were required. That extended the obligation of the doctor. To suggest that a person should be entitled to receive a certificate from a doctor whenever and for whatever he required it was going too far. To widen the obligation further would meet

with resistance from the profession. The amendment was withdrawn.

DIRECTION AND DISTRIBUTION

On Clause 34 Mr. J. S. C. REID moved to leave out the greater part of the Clause. He said it was proper that the House should come to a decision on this and subsequent Clauses which had alarming possibilities for the independence and freedom of the profession. He proposed to exclude from Clause 34 the words which limited the right of doctors to go on the list in an area with those who were in practice in that area before the appointed day. By his amendment any doctor would be entitled to go on any list in any part of the country where he offered his services, provided he was not personally objectionable. In committee it had appeared that the basis of these Clauses was the Government opinion that there was something evil about the purchase and sale of goodwill, and that the Clause controlling the movement of doctors was a necessary consequence of the abolition of the doctor's right to sell his goodwill. Mr. BEVAN had not made a case that control of the movement of doctors was necessary. The strict limitation of movement proposed in the Clause was uncalled for even in to-day's circumstances. When this Bill came into operation with 100% of the population available for capitation fees, of whom he estimated about 90% would come into the scheme, there would be little difficulty in getting doctors to go to what were now difficult areas. The problem could be cured without any of the restrictions proposed by Mr. BEVAN. There was no justification for this jurisdiction being conferred upon the Medical Practices Committee. When a vacancy occurred existing partners were not allowed to choose a practitioner they wished to come into their partnership. The question was to be remitted to the Local Medical Committee. He did not think this was for the good of the profession or for the good of the country. It was quite clear that the Minister wanted to dictate to the doctors.

Mr. BEVAN said: "Certainly not!" The buying and selling of practices was repugnant to the Government. That was the first principle, and another was that Parliament should seek to bring about an equitable distribution of a general practitioner service. These principles necessarily implied that Parliament must set up machinery for the distribution of general practitioners. The doctors would normally be consulted on the filling of a vacancy, and thus they would have a greater privilege than the members of any other profession. Then the Executive Council would make the appointment and the Medical Practices Committee would confirm it. Mr. REID's amendment would wreck the whole Bill.

Sir HENRY MORRIS-JONES said Mr. BEVAN was taking away from the doctors a right which they had now and they had never asked for that right to be taken away. Mr. BEVAN said Sir Henry was right, but the doctors were not yet in sole control of the country. It was Parliament which had decided that the country was going to have a public health service, and therefore it must construct the principles which made that service practicable. Mr. REID had suggested that the doctors should have the right to enter the public service at their own will in any part of the country, claiming something which no other profession had. If doctors were allowed to go anywhere the scheme would be impossible to implement because the Ministry would never know where the doctors were going until they had gone. He did not say that if the doctors did not enter the public service they should be under restraint. They could put up their plates wherever they liked, but if they wished to receive remuneration from the public service one condition was that the doctor should not serve where his services were not required. This was a negative control over distribution.

Mr. HENRY STRAUSS did not believe it to be in the public interest that any district could say: "There are enough doctors here." The doctors in the barred district would be freed from all stimulus to efficiency. Mr. LINSTED pointed out that so long as a man was not going as a doctor but only as an assistant this clause did not apply. He suggested that as assistants were exempt from the Clause the case for direction in order to secure a proper distribution of medical practitioners was not proved. Mr. WILLING supported the amendment, and after further discussion it was rejected by 277 to 128.

SALE OF PRACTICES

Mr. REID moved to leave out Clause 35 prohibiting the sale of medical practices. He said that Conservatives did not agree that there was any intrinsic reason for abolishing the sale of goodwill. The House had not been told of any practical benefit which that change would achieve. If Parliament did desire to stop the sale of goodwill they did not need so complicated and so oppressive a clause as Clause 35. It would be easy to draft a clause which would provide that there should be no

direct sale, and that other transactions which could be proved to be a cloak for payments which were really payments for goodwill would be illegal on being so proved and would be subject to penalties. The deliberate offender could be caught with a simple clause because intent could be proved against him, but under the present Clause thousands of innocent transactions would be impeded and probably there would be only half-a-dozen prosecutions in the end. For the sake of one or two people scattered over England a doctor or his widow could not sell his house to another doctor or make any partnership agreement with another doctor or take on another doctor as an assistant without going to the Medical Practices Committee under subsection 10.

Mr. BEVAN pointed out that subsection 10 had been put in as a protection because he was of opinion that many arguments previously advanced by Mr. Reid were sound. The State had set aside £66,000,000, which the medical profession agreed was extremely generous, and the State was therefore entitled to take precautions to ensure that any doctor did not get the benefit twice. The original Clause was drawn very tightly but had been amended in committee, and the doctor now had to obtain from the Medical Practices Committee, mainly a professional body consisting of his colleagues, a certificate that a transaction was reasonable. That was a defence against any action being taken. In a later amendment Mr. Bevan said he introduced the word "knowingly" to make clear that there must be awareness of the offence before it had been committed. In all the circumstances every kind of protection had been given in this matter.

After further discussion Mr. Reid's amendment was defeated by 305 to 110. On the Motion of Mr. KEY consequential and drafting amendments were made in the same Clause including the insertion of the word "knowingly," as promised by Mr. Bevan, and a provision that the sale of a partnership to an assistant shall be deemed to have been effected at the time when the remuneration was fixed.

DISQUALIFICATION OF PRACTITIONERS

On Clause 42 Mr. REID moved, where the Clause provides for inquiry into cases where it is represented that the continued inclusion of a person in a list would be prejudicial to the efficiency of the service, to add the words: "By reason of his failure properly to provide the services which he has undertaken." In committee the Minister had said that the local executive would decide whether a man was a bad influence. Mr. Reid contended that the local executive had to decide nothing of the kind. It had to decide whether a man had fallen short in certain specific respects. Under the form of words in the Bill it would be possible for a doctor to be dismissed by the Minister merely because the Minister thought he was a bad influence without anything having been proved. Mr. Bevan had gone on to say that the Government could not admit that the Courts should interpret whether the doctor had been in fact a good servant of the people. Mr. Reid remarked that this was a more authoritarian approach than the public was accustomed to in this country.

Mr. BEVAN asked what was wrong with the words "bad servant" and "bad influence"? Before the doctor could be removed something had to be proved against him. It was not enough for the Minister to dislike his voice or his politics. Something had to be proved which made him, in respect of his being a doctor, a bad public servant. The doctor might not be tending his patients properly although he might be a good doctor. All kinds of reasons might make him a bad servant on to employ and the Tribunal must take them into account. They must always be concrete and particular reasons. It was for the General Medical Council to pass judgment upon a doctor as a doctor, but when a doctor was a servant of the National Health Service and fell short of what was required in rendering certain services, he was not a proper servant and was liable to be removed. The amendment was withdrawn.

THE RIGHT OF APPEAL

Mr. BEVAN moved to insert in the same Clause the words: "(4) An appeal shall lie to the Minister from any direction of the Tribunal under the last foregoing subsection and the Minister may confirm or revoke that direction." Mr. Bevan recalled that in committee the words "appeal to the Minister" in the case of a dismissal of a doctor had been deleted and that a proposal to substitute an appeal to "a High Court judge" had not been substituted. He said this was a matter of importance. The Minister and the doctor, or rather the Executive Council and the doctor, were in some respects in the relationship of employee and employer, and it would be perfectly proper if the employer could dismiss the employee without any redress. But it had seemed to him that it would be difficult if not impossible for doctors who were removed from the service to obtain a livelihood outside, and that special

protection should be given to the individual against any possibility of injustice. Mr. Bevan said that by his own plan he interposed a tribunal between himself and the Local Executive Council, which might for one reason or another be prejudiced. The Chairman of the Tribunal would be a local person appointed by the Lord Chancellor but not a dentist or doctor. If the Tribunal decided that the Local Executive was correct in its decision, the doctor had a further appeal to the Minister, who would then institute an inquiry. He could appeal on one of three grounds. First, that the procedure laid down for his trial had not been carried out; second, that the Tribunal had exceeded its powers; third, that the principle of natural justice had been violated. Conservative members suggested that instead of the doctor appealing to the Minister he should have the right to appeal to a judge of the High Court. This would put the judiciary in a queer relationship with the legislature. How could a judge of the High Court decide better than the Executive Council whether a doctor had been an efficient servant? The qualitative significance of facts in the health service was a matter which only those who knew the service could judge. Supposing that a doctor appealed to the High Court judge against a decision of the Tribunal and the High Court judge decided that the man was restored to the list and then a week afterwards a child died in circumstances clearly pointing to negligence by the doctor, a question were put in the House of Commons to the Minister of Health, the Minister's reply would be: "I did not appoint the doctor: it was the High Court judge." That would be a ridiculous situation.

Dr. MORGAN said he would have to vote against the Government or abstain from voting on this issue if it went to Division. The aggrieved person should have the right of appealing to a higher court. He would be better to go before an experienced judge accustomed to weighing evidence. Mr. WILLINK said the issue was one of first-class importance and there ought to be an appeal to a court of law.

The House rejected the proposed amendment by 296 to 12. It then accepted an amendment proposed by Mr. KEY which would give a doctor a right of appeal to the Minister for the removal of disqualification. On Clause 47, on the decision of disputes, the House agreed to an amendment proposed by Mr. KEY removing from the Clause provision for the appointment of a person to act on behalf of the Minister. Mr. Bevan explained that this was in fulfilment of a promise made in committee.

HOSPITAL MANAGEMENT COMMITTEES

On the Third Schedule Mr. WILLINK moved to insert a provision that a hospital management committee should have power to co-opt not more than three persons to be members of the committee. He said that as the Bill stood these committees were entirely nominated by the Regional Hospital Board. Mr. BEVAN said he could not accept the amendment, which had already been considered in committee. The amendment was withdrawn and the committee agreed to an amendment proposed by Mr. KEY providing that no member or officer of any body or committee named in the Schedule should be debarred from being elected a member of the House of Commons. Minor amendments were made in the Fourth and Fifth Schedules and the remaining Schedules. The Report stage was thus completed and the Bill was set down to be read a third time.

Third Reading

Mr. KEY on July 26 moved the Third Reading of the National Health Service Bill. He said the fully developed services which would be provided under the Bill would give early and adequate attention to the onset of diseases, the results of accidents, and the effects of increased age. Since the Bill received a Second Reading, no major change had been made in it. Some might think that another method of distribution of practitioners was preferable to what was adopted in the Bill, but when the things had been adequately considered the will of the majority must prevail, and the duty of all was to co-operate in making the service a success. He was convinced that doctors, nurses, doctored, hospital governors and municipal councils, Ministers of Health representatives and health workers would come together to work out the details of this great service. For regional boards, management committees, and house committees, the Bill widened and extended the opportunities for voluntary service in management and control of hospital institutions. By extending to these boards and committees the power to accept gifts and hold endowments it encouraged local voluntary efforts. By guaranteeing maintenance of the institutions and provision from public funds of money for normal day-to-day expenses, it set free voluntary contributions for purposes likely to appeal to private donors. He denied that the Bill mutilated the structure of local government. He remarked that all appointments to the bodies which would

arry out the Minister's powers were to be made after consultations with the organizations concerned. In the general practitioner service only one change had been made: the Minister's control, to a negative extent, in the distribution of doctors through the Medical Practices Committee. No power of a new kind in this department had been conferred on the Minister by the Bill. His powers were of a kind which had been enjoyed for over thirty years by Ministers in relation to benefits under the National Health Insurance scheme. He denied that the Bill appropriated trust funds and benefactions in contempt of the wishes of donors and subscribers. The charge that the Bill undermined the freedom and independence of the medical profession was perversion *par excellence*. Every doctor was free to enter this service or not as he chose. If he entered he was free to take or reject patients. If he entered he was free—an astounding thing to many—to accept private patients if he wished. But if he entered the service he did so on the understanding that he accepted and observed the essential conditions of the service which he joined. Had the freedom of the medical practitioner in a municipal or voluntary hospital been undermined because he accepted a salaried appointment in the hospital concerned? No body of public or of private employees ever had the same freedom as the medical profession would have under the Bill. The chairman of the Medical Practices Committee, which was the general practitioner's real employer, must be a doctor, and six out of eight of the members must be doctors as well, five being actively engaged in practice. Misrepresentation could sink to no lower depth than to say that this undermined the freedom and independence of the profession. The case for the Bill was proved up to the hilt.

REJECTION MOVED

Mr. Linstead moved that:

This House, while welcoming a comprehensive health service, declines to give a Third Reading to a Bill which discourages voluntary effort and association; mutilates the structure of local government; dangerously increases Ministerial power and patronage; appropriates trust funds and benefactions in contempt of the wishes of donors and subscribers; and undermines the freedom and independence of the medical profession to the detriment of the nation.

He said the Bill would provide a dull, uniform, unimaginative, and pedestrian health service. Lack of co-ordination would not be removed by the Bill. Half-a-dozen Government Departments would still be responsible for types of health service and local service divorced from one another. There would be health centre services where three or four authorities would meet in the same building. The Bill did not use the circumstances of local growth but uprooted the present system, gathered it into the centre, and then artificially devolved it outward. There was maximum control of the professions, with every inducement to compel medical practitioners to come into the scheme. A bribe of £66,000,000 of the taxpayers' money was being used to sweeten the Bill for the medical profession. There was excessive concentration of power and patronage in the hands of the Minister. Mr. Key had pointed out that nomination would be exercised by the Minister after consultation with appropriate organizations. But these organizations would be selected by the Minister, and their chairmen, in many cases, would be selected by the Minister alone without consultation with anybody. There would be an administrative bottleneck in Whitehall. The Bill would kill the voluntary hospitals, and would prevent people giving local voluntary service because it would amalgamate hospital committees into committees managing thousand-bed units. The Government would place hospitals under remote control by regional boards, many of them 100 miles away from some of the hospitals they administered. Provisions in the Bill would put the medical profession in chains. Prohibition of the sale of medical practice removed an honourable inducement to give increased and better service. The Bill interfered with the rights of doctors to choose their partners. It deprived a practitioner who stayed outside the scheme of access to hospital beds. It supplanted by new tribunals the professional disciplinary tribunals which had looked after the discipline of the great profession for a century. In the course of a few years a free profession would cease to exist and the country would have reached the goal welcome to Labour M.P.s—a salaried medical service.

Cmdr. Maitland seconded the amendment.

UTILITY MEDICINE IN UTILITY HOSPITALS

Mr. Eccles said his father, grandfather, and great-grandfather all qualified at St. Bartholomew's Hospital and Lord Dawson of Penn had been his father-in-law. If Lord Dawson had lived two more years the House would be debating a better Bill. The essence of the controversy between the medical supporters and opponents of the Bill was the doctor's responsibility. The Bill laid down that the doctor should be responsible

both to his patient and to the State. Mr. Bevan had never appreciated the consequences of his solution to this dilemma of responsibility. The Bill took away the single duty to the patient. Doctors he had known would have protested strongly against the doctrine of utility medicine in utility hospitals. Patients had confidence in a hospital because all doctors, whether general practitioners or specialists, learned their medicine under men who had imbibed the tradition of undivided responsibility of the independent doctor to his patient. The Minister recognized the value of this tradition by the treatment which he gave to the teaching hospitals.

Mr. BEVAN asked Mr. Eccles to say in what part of the Bill the Minister or any of the Boards interfered with the professional conduct of the doctor toward his patient. Mr. ECCLES replied that throughout the Bill the doctor was responsible to agencies set up by the Minister. Mr. BEVAN said Mr. Eccles was wrong.

Dr. STEPHEN TAYLOR said the real danger about the Bill was that it gave the doctors too much freedom. There was a danger that Parliament might impose a medical dictatorship. Medical efficiency was not all it should be in many parts of the country. Medical qualifications were not difficult to obtain if one had the money and could stay the course. At the bottom, one third of the medical profession was pretty low and he believed that a special form of inspection might help efficiency. The B.M.A. would cut off its nose to spite its face if it did not come in when this Bill became law.

Mr. HEATHCOTE AMORY said the Bill, throughout, seemed to regard doctors as a body of men who, given the opportunity, would abuse their positions.

Mrs. RIDEALGH asked whether the Minister would help doctors who would be in difficulties during the transitional period. She had been told there were 500 affected.

A PRACTICAL DIFFICULTY

Sir E. GRAHAM-LITTLE said there was a practical difficulty about the Bill. Good authorities estimated that if the Bill was put into operation at least three times as many doctors would be wanted as were now available. The present strength of the medical profession in practice was about 52,000. Nearly the whole of that total were now members of the B.M.A. The resolutions of that Association were surely important for the Minister to consider. All the discussions in the medical press and at meetings pointed to a great disinclination to accept service under the Bill. The doctors would not strike. That was a ludicrous suggestion. Most would say: "We do not want to work under a State service and we shall continue to work as we are now." As a member of the medical staff of a great teaching hospital he said it was wrong to suggest that the hospital system had failed to give a general service to all classes of the community, except, possibly, the middle-class. The acid test of the efficiency of a hospital was medical research. For 400 years the voluntary hospital and what was now called the municipal hospital had existed side by side, but the voluntary hospital had done the research. Mr. Willink, in his White Paper of 1944, had claimed the direction of doctors, but finally repudiated that power. It was in no way repudiated by Mr. Bevan. How many of the 50,000 active practitioners would join the service? Not more than half were likely to join the service, but the Minister needed 150,000. Various efforts had been made by the Government of Australia to introduce a State medical service, but they had uniformly failed. The N.H.I. Act of 1911 started under a handicap and had never been the success it might have been had there been greater circumspection in the approach to the profession. A greater circumspection in approach was needed now. There was no possibility of 100,000 doctors being trained in time for the appointed day under the Bill. The Dominions' offices were overwhelmed by applications from demobilized young doctors to go away from this country. To South Africa 100 of the younger doctors were emigrating, to Australia 150, and the figures for Canada and New Zealand were similar.

Sir Henry MORRIS-JONES said Mr. Bevan could not complain of an obstructive opposition to the Bill. Mr. Bevan and Mr. Key had in this Bill achieved a Socialist programme and were carrying through a great measure of nationalization. The doctors in the service became servants of the State, and for the first time people would be precluded from earning a living in places where they wished to earn it.

Mr. SOMERVILLE HASTINGS congratulated Mr. Bevan on a great Bill. It would provide, for the first time, a possibility of complete union between the preventive and the curative services. For the first time there would be a unified hospital service under the Minister. It had been noted in Committee that Mr. Bevan inclined to give more power to the hospital management committees and less to the regional hospital boards. Mr. Hastings warned him of the danger of this. The

use of beds must not be left entirely to the hospital management committees, nor should the higher appointments be so left. In statistics a uniform method of recording would be advantageous.

Dr. MORGAN said the bulk of the doctors, if they could be rid of the political prejudice from the other side, would work the Bill.

Mr. WILLINK said all parties were committed to sweeping changes in the sphere of public health. No reference had been made during the debate to the appointed day being April 1, 1948. That was at least a year, and probably two years, later than Labour M.P.s had thought a National Health Service would come into operation. But for the increased difficulties which the Minister had put upon his Department and on local authorities by his scheme, the Bill could have come into operation at least nine months earlier than it would do. He wished to bring to Mr. Bevan's attention the obscurity of the law relating to mental health as it emerged from the Bill.

It was, Mr. Willink remarked, one of the features of this Bill that mental health was brought, as it should always have been, within the sphere of the general health service, but the law with regard to mental health as it emerged from the Bill was lamentably obscure. He hoped the Minister would make rapid progress in clearing this field.

Mr. Willink said that since the Second Reading the position of the Central Health Services Council had been improved and that the individual hospital had been made a legal person with power to receive money and other property. The ridiculous remoteness of the Medical Practices Committee had been mitigated by a promise that in substance the doctors of the district would make the effective decisions on the succession to practices. The oppressive provisions of Clause 35 had been substantially improved. But the Bill still enabled extraordinary things to be done, and the Conservative Opposition objected to it because it discouraged voluntary effort and association. Every voluntary hospital was being taken over by the State and the Bill contained a provision enabling any future medical institution which might be set up to be taken over by the Minister. There was no security for any medical curative institution. Money given for the benefit of a locality or of a particular hospital would on April 2, 1948, become the property of the Minister of Health, to be put wherever he liked. The Minister would control the Hospital Endowment Fund. Local government was mutilated by removal of responsibility for any form of hospitals and by separation, on an unexplained basis, of the hospital service from the clinic service. The Minister prided himself on creating an entirely new hospital service. Was this the time for the Government to take on itself that extraordinary function? The Minister was taking power to direct the management of every place in the country where a citizen could obtain hospital care and even of the teaching hospitals. The Minister would redistribute £32,000,000 of charitable funds over England and Wales and did not even propose to bring his scheme before the House. There was no limit on what the Minister did with the money belonging to the voluntary hospitals. The Minister's unjustified insistence on a basic salary for every doctor was a first instalment of what Mr. Key had admitted to be inconsistent with people choosing the doctor they wanted. There was direct and indirect pressure in the Bill upon the medical profession to enter the service and insecurity for all who came in because of the absence of any appeal from a tribunal two-thirds lay, save to the Minister. Partnerships were threatened. Partners were no longer to be

THE MINISTER'S REPLY

Mr. BEVAN said he had a light task in replying. He rejoiced at the measure before the House was entirely different from the one on which Mr. Willink had laboured, which was unpalatable and unpopular. If Parliament entered into a contract with the citizens, collected from them a contribution, and in return gave a certain service, how could the contract be carried out if it was operated through an independent and self-motivating body? In regard to hospitals, Mr. Bevan asked how he could guarantee that the citizen in one part of the country would get the same service as a citizen in another part if the instrument to give that service was an independent, autonomous body. Every single instrument of the Bill must be an agent of the Minister. It was then necessary to ensure that the service did not become too centralized. Therefore the scheme provided for Regional Boards, management committees and house committees. The only voluntary part of the hospital system destroyed by the Bill was the necessity to sell flags and collect money—the indignity of having to collect money by private charity. The reason behind the bitterness of members opposite was that the Bill took away from them one of their chief sources of social and political patronage. It was notorious that first-class surgeons, gynaecologists, and general practitioners had from time to time to desert the practice of their

profession in order to seduce millionaires to provide money for teaching medicine. A number of people sat in the House of Lords in consequence of their benefactions. It was established in the medical profession that one of the chief qualifications of some of the ornaments of the profession was that they were able to attract money for the hospitals from rich individuals. The only aspect of the voluntary system which the Bill destroyed was one deeply repugnant to a civilized society, that the care of its sick should be dependent on the benefactions of well-to-do persons.

Voluntary work would be more efficient in future because it would be emancipated from financial considerations. In the hospital scheme of the future the patient, instead of receiving incompetent treatment in a small hospital, was taken to another hospital where he got specialist treatment and the endowment of the local hospital followed the patient. The Opposition had put down an amendment to the Third Reading to inhibit the medical profession. He was astonished that the leaders of the doctors had identified themselves in a spirit of partisanship with the Conservative Party. The spokesmen of some elements of the medical profession had become the most reactionary politicians in Great Britain. He deplored the medical profession being involved in these discussions and in this controversy. The medical profession, as a whole, would work this scheme wholeheartedly. In a recent plebiscite of the medical profession they decided by a majority in favour of the abolition of the sale and purchase of practices. Why should the young doctor have to seek the assistance of a usurper before he could practise? Why should the medical profession be placed in the toils of usury on the excuse that by doing so a competitive spirit was maintained in medicine? What was wanted was not a competitive but an emulative spirit. Effectively to man the medical profession it was necessary to derive doctors from lower income groups than hitherto. Therefore it was essential to start them off in a proper fashion. In no part of the administration of the Bill had the Minister of Health, or any other authority, the slightest control over the professional conduct of the doctor. Under the scheme doctors were not State servants. They were in contract with a body over which they themselves had considerable influence. They were not in contract with the Regional Boards or with the Minister. Doctors would have more protection under the scheme than they had at present. Under the scheme they had appeals to the Tribunal. They were the most protected profession in the country. He remarked that he had no time to describe the positive merits of the Bill. The Government hoped now to leave controversy behind and to get the co-operation of the medical profession and of all health workers because without that co-operation the scheme was bound to fail. "Now that we are reaching the conclusion let us hope that the echoes of controversy will die down, and that what will reach our ears will not be the declamations of partisans but the whispers and piteous appeals of sick people all over the country, of the weak and distressed who are reaching out their hands to this House of Commons to give them succour and assistance in their difficulties. I believe that eventually it is that small voice that will be heard and will be the most influential and not the raucous declamations of controversialism."

The amendment proposed by Mr. Linstead was then rejected by 261 to 113 and the Bill was read a third time.

Need for Sanatoria

Dr. SEGAL asked on July 18 whether Mr. Bevan knew of the increasing shortage of sanatorium accommodation, and whether he would take joint action with the responsible authorities to retain some of the existing E.M.S. hospitals for conversion into sanatoria.

Mr. BEVAN replied that the crucial factor was not shortage of accommodation but the dearth of nurses and other hospital workers, which precluded the staffing of sufficient additional beds. Every effort was being made to remedy this.

Inspectors for Experiments on Animals.—Asked on July 11 about the appointment of inspectors for investigating experiments by vivisection, Mr. EDE said he would be glad to consider candidates with veterinary qualifications, but medical qualifications were essential in an inspector, and it was rare to find a candidate qualified in both professions. Concerning the recent case at Oxford—which, he believed was still *sub judice*—the premises had been visited the previous month by a Home Office inspector before the outbreak of disemper which was mentioned in the proceedings.

Notes in Brief

Work in connexion with accommodation and amenities for domestic staffs of hospitals has not been singled out for a particular priority. As in other classes of case, priority may be granted where the work is of particular urgency, and licences may also be given for less urgent work that can be undertaken with labour and materials not required for priority work.

The Ministry of Health Standing Committee on Medical and Nutritional Problems includes the following. *Ministry of Health*.—Mr. Wilson Jameson, Dr. W. A. Lethem, Dr. H. E. Magee, Dr. D. M. Taylor. *Ministry of Food*.—Lord Horder. *Ministry of Education*.—Mr. J. Aislon Glover. *Medical Research Council*.—Sir Edward Mellanby, Prof. S. J. Cowell, Dr. B. S. Platt. *Department of Health for Scotland*.—Sir Andrew Davidson. *Ministry of Fuel and Power*.—Mr. S. W. Fisher. *Ministry of Labour and National Service*.—Mr. E. R. A. Merewether.

The Pneumoconiosis Research Unit of the Medical Research Council has opened a clinic at the hospital at Llandough for the study of certified cases to determine the possibilities of direct treatment. Similar investigations are being made among tin miners in Cornwall, including the possibilities of treatment by the inhalation of finely powdered aluminium. A clinical study of working miners in selected mines in South Wales, in relation to dust and other environmental conditions, is about to start.

According to returns from the local authorities concerned, 66% of the child population up to age 15 were immunized against diphtheria in Manchester at Dec. 31, 1945, 49% in Ashton-under-Lyne, and 52% in Oldham.

Except where considerations of health or safety make such a course undesirable all paraplegic pensioners will, in future, be eligible for the supply and repair of a motor invalid tricycle at State expense.

The Services

Major-Gen. J. C. A. Dowse, C.B., C.B.E., M.C., late R.A.M.C., has been appointed Honorary Physician to the King in succession to Col. (Temp. Brig.) H. A. Sandiford, M.C., late R.A.M.C., retired, and Major-Gen. E. A. Sutton, C.B.E., M.C., late R.A.M.C., has been appointed Honorary Surgeon to the King in succession to Major-Gen. G. A. Blake, C.B., late R.A.M.C., retired.

Surg. Cmdr. H. L. Cleave, R.N., has been appointed O.B.E. (Military Division) and Surg. Lieut.-Cmdr. J. C. Wyatt, R.N., and Surg. Lieut. C. A. Jackson, R.N.V.R., have been appointed M.B.E. (Military Division) for outstanding services while prisoners of war in the Far East.

Surg. Cmdr. V. F. Walsh, R.N., and Temp. Surg. Lieut. D. R. Syred, R.N.V.R., have been mentioned in dispatches, and Surg. Lieut.-Cmdr. D. N. Ryalls, R.N.V.R., has been mentioned in dispatches posthumously for good services while prisoners of war in the Far East.

Majors S. M. Banfill, J. N. B. Crawford, and J. A. G. Reid, R.C.A.M.C., have been appointed M.B.E. (Military Division), and Major G. C. Gray, R.C.A.M.C., has been mentioned in dispatches, in recognition of gallant and distinguished services while prisoners of war in the Far East.

Capt. C. T. Robertson, R.C.A.M.C., has been appointed M.B.E. (Military Division) in recognition of gallant and distinguished services while a prisoner of war.

Medical News

Arrangements have been made to hold the next congress of the International Surgical Society in London from Sept. 14 to 20, 1947. The president will be Dr. Leopold Mayer of Brussels, and the general secretary of the society is Dr. L. Dejardin of Brussels. An interesting programme is being prepared. Local arrangements will be in the hands of a British committee of which Prof. G. Grey Turner is chairman, and Mr. H. W. S. Wright (9, Weymouth Street, Portland Place, W.1) the honorary secretary.

On the recommendation of the honorary managing committee of the Bureau of Hygiene and Tropical Diseases, the Secretary of State for the Colonies has confirmed the appointment of Dr. Charles Wilcocks as director of the Bureau with effect from April 1, 1946, and has appointed Dr. H. J. O'D. Burke-Gaffney to be assistant director with effect from July 16, 1946. Dr. J. F. Corson, who, since July, 1943, had given his help as acting assistant director of the Bureau, retired on June 30.

The Fellowships offered by the Commonwealth Fund of New York to British graduates for tenure in American universities have now been resumed after interruption by the war. The committee of award have made the following appointments in medicine for 1946-7: A. H. Cruickshank, M.D., to Johns Hopkins University; A. M. McKelvie, M.B., Ch.B., to the Mayo Clinic.

A site is being sought in London by the Save the Children Fund for a memorial to children of all countries who lost their lives during the war.

Sir Comyns Berkeley, F.R.C.P., F.R.C.S., F.R.C.O.G., who died on Jan. 27, left £123,659, the residue of which goes to Gonville and Caius College, Cambridge, for the provision of medical fellowships.

Universities and Colleges

UNIVERSITY OF LONDON

Westminster Hospital Medical School

Lord Woolton will deliver the Inaugural Address at the opening of the new academic session in the Sir Edward Meyerstein Lecture Theatre of the School on Monday, Oct. 7, at 3 p.m.

An entrance scholarship examination in anatomy and physiology will be held on Sept. 11 and 12. Applications for further particulars must reach the secretary, Westminster Hospital Medical School, 17, Horseferry Road, S.W.1, by Aug. 16.

The following candidates have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN MEDICAL RADIOLOGY.—P. H. Beamish, F. G. Callus, M. C. Connell, M. A. Egan, M. A. FitzGerald, E. H. Hansoo, F. L. McKelvie, M. Mandelstam, Gwenllian B. Morgan, B. Navid, J. F. Nicholl, E. J. Richardson, W. V. Taylor, B. C. H. Ward. *Part I*: L. Charney, M. G. E. Shakkankiri, K. N. Tankariwala.

UNIVERSITY OF BIRMINGHAM

The following appointments to full-time Clinical Chairs of Medicine, Surgery, Obstetrics and Gynaecology, and Paediatrics and Child Health are announced:

Chair of Medicine: W. M. Arnott, M.D., F.R.C.P.Ed. *Chair of Surgery*: F. A. R. Stammers, C.B.E., F.R.C.S. *Chair of Obstetrics and Gynaecology*: Hilda N. Lloyd, F.R.C.S., F.R.C.O.G. *Chair of Paediatrics and Child Health*: J. M. Smellie, M.D., F.R.C.P.

UNIVERSITY OF EDINBURGH

At a Graduation Ceremony held on July 24 the following medical degrees and diplomas were conferred:

M.D.—A. El Shaked, J. Innes, R. J. G. Ratcliffe, J. S. Robson, D. C. Ross, W. D. Willart.

Ch.M.—J. S. Smellie (gold medal), R. Strang.
M.B., Ch.B.—Grace Barker, Patricia M. Barraclough, Elizabeth L. Batchelor, Margaret R. Bate, F. A. Beale, Fiona M. Bennett, H. L. Binnie, W. L. Blackett, W. J. O. Box, Mary M. M. Boyd, E. R. Brooks, J. R. Brotherton, J. Brown, Pamela J. Brown (née Rickwood), S. P. Bruce, Mary C. Buchanan, Katharine A. Burn-Murdoch, J. Burton, A. Cameron, W. W. Campbell, I. W. Clark, Barbara E. Clayton, D. C. Cockburn, Jole L'E. K. de Lingen, A. C. Douglas, D. Duncan, J. A. Ewing, R. M. Foster, A. D. B. Fotheringham, R. Frater, E. N. S. Fry, K. G. Gadd, W. R. Galloway, Constance A. Gibbs (née Mitchell), R. A. F. Gilbert, J. M. Gill, R. Gillott, Philippa A. Glyn, A. Goldberg, R. H. Gosling, Jessie E. J. Grainger, E. R. Gunn, Sheila I. Haldane, K. C. R. Halliday, T. L. Henderson, J. S. Holden, R. Houston, Moira B. Hughes, Elizabeth S. Humble, R. C. Humphreys, Morag L. Insley (née Henderson), A. S. Ireland, G. Irvine, A. B. Jamieson, D. A. L. Jones, J. D. Kerr, Alison B. King, Isabella Kingan, Charlotte M. M. Kirkcaldie, L. C. S. Knight, R. R. Lam, S. G. E. Lavery, Rosemary W. Lawrence, Isabel J. K. Ledger, Mary K. Lethem, J. C. Lewis, K. A. Lim, P. D. Livingstone, Helenor F. Lochhead, J. A. Loraine, Ethel M. J. Loudon, A. C. McDougall, Margaret M. MacDougall, W. A. MacDougall, P. C. MacGillivray, R. C. MacGillivray, D. M. MacKay, I. G. MacKenzie, D. L. MacKinnon, J. MacLean, A. McNah, R. C. Macnair, Betty Mallace, Dilys Mannars, T. S. Martin, K. W. Matheson, Katherine-Alice Mercer, J. D. C. Millar, F. R. D. Moett, R. W. Murray, Irene M. J. Monaghan, Isabel S. Mowat, Elspeth M. Orr, O. E. Owen, J. R. Page, H. L. Park, E. L. Rawson, A. Reid, D. Reid, Myrtle V. Richards, B. Ruehner, W. R. St. Clair, Kathleen G. Scott, Anne K. I. Sellers, W. L. Sewell, Helen M. Shearer (née Lenman), C. G. Sim, D. A. Sime, D. C. Simpson, K. Sinclair, G. M. M. Smibert, L. S. Smith, J. F. Sommerville, A. R. Sommer, J. O. Taubman, Emily D. J. Todd, C. H. M. Walker, C. H. Wheatley, Rachel B. White, J. W. Whittick, A. J. Williams, C. E. Williams, A. T. Wilson, J. T. Wright, D. Yuille, Monica M. Zealley.
B.Sc. (Department of Pure Science)—Mary C. Buchanan, M.B., Ch.B.

DIPLOMA IN PSYCHIATRY.—J. B. Methven.
DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—W. Bain, J. A. P. Bouton, G. Buchanan, C. W. F. MacKay, J. P. Mehrotra, K. D. Moynagh, W. O. Petrie, J. M. Smith.

POLISH SCHOOL OF MEDICINE AT EDINBURGH

M.D.—K. Durkacz, L. Kulczycki, Magdalena K. Munk, R. Rejthar, O. Rymaszewski, T. J. Szczesniak, H. Wójcicki.
M.B., Ch.B.—A. Bobak, W. Galecki, K. Getta, Z. Giedrys, E. Gruhsztajn, W. Kacmarek, A. Kuroski, T. Lahajek, Z. Liskowicz, Z. Milewski, Liwia Mitis, K. Sztabert, L. Wachala, A. Wlozczewski.

The following scholarships, bursaries, prizes, etc., were awarded to the Faculty of Medicine: *Cameron Prize in Practical Therapeutics*: A. Szeot-Györgyi, M.D., Ph.D., professor of medical and organic chemistry in the University of Szeged, Hungary, in recognition of his distinguished contributions to the knowledge of vitamin C. *Entles Scholarship and Leslie Medal and Scottish Association for Medical Education of Women Prize*: Rachel B. White. *Chiene Medal in Surgery*: J. S. Smellie. *Mouat Scholarship in the Practice of Physics*: Royal Victoria Hospital Tuberculosis Trust Medal, and *Thomson Memorial Medal in Child Life and Health*: J. A. Loraine. *Stark Scholarship in Clinical Medicine*: R. F. Robertson. *Buchanan Scholarship in Midwifery and Gynaecology*: Mary M. M. Boyd. *James Scott Scholarship in Midwifery and Gynaecology*: R. C. MacGillivray. *Vans Dunlop Scholarship in Materio Medica and Medicine*: J. A. Loraine. *Prox. acc.*: R. F. Robertson. *Vans Dunlop Scholarship in Pathology and Surgery*: H. A. F. Dudley. *Dorothy Gilpin Memorial Prize, Annandale Medal in Clinical Surgery*, and *Lawson Gifford Prize in Obstetrics and Gynaecology*: Barbara E. Clayton. *Beane Prize in Anatomy and Surgery*: W. R. St. Clair. *Prox. acc.*: Barbara E. Clayton. *Keith Memorial Prize in Systemic Surgery and Pathology*: Margaret Stirling. *Colonel Thomas Biggam Memorial Medal and Prize in Pathology*: Rosemary H. M. Davie. *Lewis Cameron Undergraduate Prize in Bacteriology*: D. S. M'Lauren. *Cunningham Memorial Medal and Prize in Anatomy and Senior John Aitken Corliffe Bursary in Anatomy and Physiology*: W. F. Coulson. *Junior John Aitken Corliffe Bursary*

Anatomy and Physiology: M. T. Lambie and (b) *Physics and Chemistry*: Anne T. Lambie.

¹ *In absentia.* ² Highly commended for thesis. ³ Commended for thesis.

UNIVERSITY OF GLASGOW

the King has approved the appointment of Robert Aim Lennie, M.D., F.R.F.P.S., F.R.C.O.G., senior obstetric surgeon in the Glasgow Royal Maternity and Women's Hospital and gynaecologist at the Victoria Infirmary, Glasgow, to the Regius Chair of Midwifery at the University of Glasgow.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At a quarterly meeting of the College, held on July 16, the resident, Dr. D. M. Lyon, intimated that the following had accepted the Honorary Fellowship of the College:

Major-Gen. Sir Alexander Gordon Biggam, K.B.E., C.B., M.D.Ed., R.C.P.Lond., Sir Henry Hallett Dale, O.M., G.B.E., M.D.Camb., R.S., F.R.C.P.Lond., Neil Hamilton Fairley, C.B.E., M.D.Melb., R.S., F.R.C.P.Lond., Sir Alexander Fleming, M.B.Lond., F.R.S., R.C.P.Lond., Sir John Fraser, Bt., K.C.V.O., M.C., M.D., R.C.S.Ed., The Rt. Hon. Lord Moran, M.C., M.D.Lond., R.C.P.Lond., Major-Gen. Sir Percy Stanley Tomlinson, K.B.E., B., D.S.O., F.R.C.P.Lond.

Dr. Ronald Haxton Girdwood (Edinburgh), Dr. Angus Henry Campbell (Redhill), and Dr. Stanley Galbraith Graham (Glasgow) were introduced and took their seats as Fellows of the College.

Major William Happer, I.M.S., f.B.E. (Edinburgh), Gordon Douglas (Edinburgh), and Mr Andrew Davidson (Edinburgh) were elected Fellows of the College.

SCOTTISH CONJOINT BOARD

The following candidates, having passed the final Examinations, have been granted the diploma of L.R.C.P.Ed., L.R.C.S.Ed., R.F.P.&S.Glasg.:

E. A. Barrett, W. R. Brown, W. S. Brown, Mary G. Buchanan,
Duncan, A. S. Dunn, Margaret W. Gerrard, R. F. Gray,
Lamond, G. A. Lawrenson, Julia I. Leitch, G. C. Mackie,
Catherine H. Mair, H. M. Mann, Jeannette B. Morrison, N. A.
Oppenheim, A. C. Pole, J. L. Quartey-VanderPuije, J. N. Rankin,
W. T. Richardson, H. K. Rose, Agnes W. M. Scott, Kirsty F.
Temple, W. P. Thomson, J. Watson, A. J. Williams.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* there was a general fall in the incidence of infectious diseases, and notably of measles 543, scarlet fever 152, acute pneumonia 62, and dysentery 26. The only disease with an increased incidence was whooping-cough 23.

The fall in measles was most marked in Essex 168, Surrey 87, Middlesex 86, and Kent 82. A small general decline in scarlet fever occurred throughout the country. The largest local variations in whooping-cough were a fall of 67 in Yorkshire West Riding and a rise of 49 in Lancashire. Notifications of diphtheria were 13 fewer than in the preceding week; the largest changes were a decrease of 14 in Cheshire and a rise of 11 in Essex. Only 61 cases of dysentery were notified—the smallest weekly total for almost four years; London had 11 and London 10 cases.

Further case of acute poliomyelitis, making 6 in all, has been reported from the Potters Bar area of Middlesex. At Exeter, North Devon, 16 cases of paratyphoid have been notified in the past few weeks.

In Scotland the notifications of infectious diseases decreased. There were falls in measles 77, scarlet fever 39, acute primary pneumonia 28, dysentery 25, diphtheria 22, and cerebrospinal fever 13. The fall in measles was in the western area, while in Edinburgh the cases increased from 133 to 165.

In Eire little change occurred in the incidence of notifiable diseases. Enteritis and diarrhoea rose by 8 to a total of 64, of which 58 were notified in Dublin C.B.

In Northern Ireland ice-cream caused an outbreak of 9 cases of diphtheria, of a virulent type, in Derry.

Week Ending July 20

The notifications of infectious diseases during the week in England and Wales included: scarlet fever 936, whooping-cough 2,474, diphtheria 247, measles 3,783, acute pneumonia 380, cerebrospinal fever 49, dysentery 60, acute poliomyelitis 10, paratyphoid 20, typhoid 6.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 13.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London); (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

U.K. OFFICE: 7, Drumshugh Gardens, Edinburgh.

ANY QUESTIONS?

Treatment of Amenorrhoea

Q.—*A healthy woman aged 24 has had amenorrhoea since the birth of her first baby in May, 1945. Delivery was normal, but low forceps were applied late in the second stage. Breast-feeding was continued for ten months. Post-natal examination revealed a rather small anteverted uterus. Chest skiagrams are normal; the urine contains no sugar or albumin. What causes the amenorrhoea? What is the appropriate oestrogen therapy, its dosage; and what are its rationale and the chances of success?*

A.—Although longer than average, the period of amenorrhoea cannot yet be regarded as outside the physiological limits—particularly as lactation was rather protracted. There is something to be said for waiting a little longer before resorting to hormone therapy, although general measures—tonics, open-air life, and vitamin E—might be tried. If menstruation does not commence in the near future complete investigation is indicated, but the cause is most likely to be a failure of gonadotrophic function of the pituitary following pregnancy and lactation. In the past this sort of case was diagnosed as hyperinvolution of the uterus, the implication being that the fault was in the uterus itself. It is now recognized that the uterine atrophy is only secondary to failure of ovarian function, which in turn is due to a pituitary fault.

Oestrogens act on the uterus, and by their use it should be possible to restore it to its normal size and possibly initiate "withdrawal haemorrhage." A suitable dose would be hexoestrol 1.0 mg., or dienoestrol 0.3 mg., thrice daily by mouth for three weeks followed by an interval of two weeks. Two or three courses may be given, but not more. Any effect is likely to be temporary, and the uterus will atrophy again when treatment is suspended. However, there is a chance that the endocrine cycle is merely in a state of "suspended animation" the oestrogen therapy may be enough to reawaken it to permanent activity. If it does not, the appropriate treatment is with gonadotrophin, but even this is only replacement therapy at a higher level.

Varicose Ulcers

Q.—*What is the treatment of varicose ulcers? Has penicillin been tried, and with what success?*

A.—Varicose ulcers are essentially stagnation phenomena due to incompetence of the valves in the superficial veins of the lower limbs. They are commonest in the lower third of the leg: on the inner side of the limb when the internal saphenous vein is involved, and on the outer side when the external saphenous vein is affected. In treatment one must recognize the importance of this gravitational reflux, and, although ulcers and the surroundings may become infected, this is usually of secondary importance. Healing may be obtained by many methods which overcome this gravitational reflux of blood. Absolute rest in bed with the limb elevated will invariably secure rapid healing in the absence of serious bone involvement, and almost irrespective of the nature of the local applications. Recurrence, however, is likely unless the incompetent veins are either controlled by elastic stockings or obliterated by means of injections or operation. In some cases healing may be obtained by one of the various types of compression

bandage, but this is not likely to be permanent, unless the veins are subsequently controlled by one of the foregoing methods. If permanent healing is to be secured in cases of long-standing ulceration, with a good pigmented scar free from tenderness and oedema, then almost all cases must be submitted to operation, as incompetent thigh veins are invariably present. Since the role of infection in varicose ulcers is relatively unimportant, it would appear on *a priori* grounds that penicillin or chemotherapy is likely to be of little use, and this is borne out by clinical experience. These may reduce infection but will not cure varicose ulcers. On the other hand, if the gravitational factor is overcome the ulcers will heal almost irrespective of the local application.

Dengue and Sandfly Fevers

Q.—*What is the aetiology of the sandfly and dengue group of fevers, and what is their relation to the so-called "short-term" and "long-term" fevers common in tropical and subtropical zones?*

A.—Although having features in common, sandfly and dengue fevers appear from cross-immunity tests to be due to separate and distinct viruses. "Short-term" and "long-term" fevers obviously include a group of ill-defined conditions, and it is therefore possible that an individual example, especially of the former, may be one of sandfly or dengue fever.

Raisins for Enuresis

Q.—*A handful of raisins at bedtime for nocturnal enuresis has, in my experience, worked well. Is there any scientific basis for this?*

A.—There appears to be no scientific basis for the use of raisins to cure nocturnal enuresis.

Chyluria Tropica

Q.—*A patient aged 27 has occasional brief chyluria following a two-year tour in West Africa. What is the prognosis? What are the chances of his developing elephantiasis of legs or scrotum?*

A.—Repeated or persistent attacks of severe chyluria may lead to debility, while the overt nature of chyluria may give rise to depression or an anxiety state. Secondary features, such as bleeding, urinary obstruction from coagula, and infection of the urinary tract, may also complicate the prognosis of chyluria. Transient or mild attacks, however, need not influence life or in themselves worsen the prognosis of filariasis, nor is chyluria especially associated with the development of elephantiasis of the legs or scrotum.

Glandular Fever

Q.—*A man of 30 had glandular fever a year ago in the Middle East, and has since had recurrences at intervals of three or four months. What are the prognosis and treatment?*

A.—Recurrences of glandular fever are extremely unusual, although a few instances have been reported. Nevertheless the diagnosis must be questioned if the haematological and serological changes are not characteristic. In the absence of clinical data it is not possible to suggest an alternative diagnosis, but other causes of recurrent lymphadenitis must be sought, and excision of an enlarged lymph node for histological examination considered. If the diagnosis of glandular fever is unassailable the ultimate prognosis is good. There is no specific treatment; but if the same group of lymph nodes is affected in each attack radiotherapy might be given a trial. It has proved effective in certain indolent cases (Kahlstorf, A., *Strahlentherapie*, 1935, 54, 459).

Malaria Prevention

Q.—*In which districts of North Africa is malaria rife? What is the most recent preventive medicinal measure, and the dosage?*

A.—Malaria occurs throughout North Africa. Control measures have greatly reduced the incidence in densely populated areas, but villages, if near permanent water collections, are liable to endemic malaria, or to epidemic malaria when climatic conditions are favourable. The disease tends to be seasonal, being absent or rare in the dry season

and showing its highest incidence in years of heavy rain. The best preventive medicinal measure available is mepacrine, 100 mg. daily, to be continued for two months subsequent to the last possible exposure to infection. This treatment causes yellow staining of the skin. Paludrine, which in field trials has proved to be more valuable, is not yet available. When obtainable the dose will probably be 100 mg. once or twice weekly.

Foreign Body in Stomach

Q.—A child of 3 swallowed a Kirby grip, and a radiograph shows it lying in the stomach. Is operation indicated?

A.—There is no need for operation so long as the grip is causing no symptoms. In time it should pass through the pylorus and travel along the rest of the alimentary tract. There is no fixed time for the safe residence of a foreign body in the stomach, and the surgeon must be guided by the likelihood of its causing symptoms. If attacks of pain, possibly due to the presence of the grip, should occur, then it would be wise to explore the abdomen, but a skiagram to determine the exact position of the foreign body should be taken immediately before the exploration.

INCOME TAX

Premiums for Sickness Insurances

N. M. asks whether premiums for sickness insurance can be treated as expenses or relief obtained in any other way.

.* The answer is in the negative; but sums received from such policies are not regarded as liable to income tax, unless they are receivable for such a long period as to become taxable as "annual payments."

Car Expenses

H. W. runs two cars and has deducted for income tax purposes one half of the whole running expenses. No replacement cost or depreciation has been claimed.

.* Unless the agreement with the local Revenue office was that one-half of the running costs would cover all the allowances due, there seems to have been no reason why in the past H. W. should not have deducted either one-half the full depreciation allowance or one-half actual replacement costs. (The "initial" allowance was not then in existence.) We advise him to lodge a claim for one-half the depreciation—calculated on both cars—for the past six years, or for such shorter period as may be justified by the facts. When the cars are sold a "balancing allowance" or a "balancing charge" will be applicable according to whether the sale price is less than or exceeds the cost price of the particular car less the aggregate depreciation allowances on that car. The cars will have to be dealt with separately, but if sold in the same year only the net amount will affect the liability.

Assistant: Car Expenses

W. E. is entitled to deduct his car expenses from his salary as an assistant in general practice. In February, 1946, he sold his car for £350 and bought another for £600. Can he claim the cost of replacement (£600—£350=£250) as an expense?

.* It is assumed that W. E. has not had depreciation allowances in respect of the old car. On that assumption the answer is, Yes—as an expense of the year 1945-6. If the new car represents an improvement on the old car (in the condition it was in when acquired), that part of the £600 attributable to improvement is a capital expense and is not deductible. We suggest, however, that in the long run it may be preferable to claim the usual allowances instead of the cost of replacement. On that basis no allowance would be due for 1945-6, but for 1946-7 W. E. can claim an initial allowance—i.e., 20% of £600=£120 and depreciation allowance—i.e., 25% of £600=£150, total £270. The depreciation allowance will be claimable for future years at the rate of 25% on the written-down value.

First Year in Partnership

P. J. will be acting as locum tenent up to Sept. 30, 1946, as from which date he will go into partnership. Car expenses will be borne by the individual partners. He is informed that from Oct. 1, 1946, to Sept. 30, 1947, he will be assessed on the current earnings for his personal income tax return. If so can the balance of the 20% initial allowance and the 25% depreciation allowance on a car bought in August, 1945, be allowed in his 1945-6 assessment?

.* Partnerships are dealt with as units for income tax assessment purposes. If P. J. is to be assessed for the year to Sept. 30, 1947, on the current year's basis it is presumably because the new firm has elected to be so assessed—which is not usual when the previous year's basis would carry a charge for the salary of an assistant or locum tenent. The "depreciation" allowance can be spread over

the year, but we are doubtful whether that would apply to the new "initial allowance." If, however, it is wholly set against the earnings for the six months to Sept. 30, 1946, the result is apparent the same over the whole financial year 1946-7. The cost of buying instruments can be allowed, but only as regards replacements; no requisitions represent an outlay of capital.

LETTERS, NOTES, ETC.

Protein Hydrolysate for Peptic Ulcer

Dr. D. McANALLY (Herts Pharmaceuticals, Ltd.) writes: I should like to make one or two comments on the answer (July 6, p. 3) to the question "Is protein hydrolysate useful in the treatment of selected cases of duodenal ulcer?" In the first place, this question is still *sub judice*; it is now being thoroughly investigated in this country, with controls, and the results of the investigation will probably be available in six months' to one year's time. I have personal knowledge of cases of peptic ulcer which have done extremely well on oral protein hydrolysates, but I should be the first to agree that carefully controlled clinical trial in this very important question is necessary. At the moment we simply do not know whether protein digestion is impaired in duodenal ulcer or not. From my own evidence, the most common and successful uses of oral protein hydrolysates are in peptic ulcer and convalescence, but the clearest clinical indication for their use is in those relatively few conditions where protein digestion is impaired—e.g., some cases of pancreatic disease. In the case of peptic ulcer it must be remembered that amino acids are amphoteric and therefore have considerable buffering power against gastric acidity, and also they supply an immediately available source of nitrogen to help in the healing of the ulcer. This, to my mind, is very important, as the diet of peptic ulcer patients is sometimes deficient in nitrogen, and healing of any ulcer is not to be expected under these circumstances. Where the power of absorption is impaired, giving amino acids will obviously not help, but where the ingestion or digestion of proteins is deficient, then oral protein hydrolysate therapy may very well be of benefit.

Intravenous Technique

Dr. D. S. JONES (Llanelli) writes: May I draw attention to two factors concerning intravenous technique? First, can the manufacturers provide more syringes with peripheral and fewer with central nozzles? Practically all manoeuvres can be carried out equally well with the former as with the latter. On the other hand, it is essential for a perfect intravenous technique to have a peripheral nozzle. Furthermore, local infiltration is facilitated by the use of this type of syringe. Secondly, I make a plea for the adoption of the smaller hypodermic No. 24 s.w.g. needles for intravenous work, the advantages being that it is easier to puncture a vein, haematomata are rare, it is less painful for the patient, and an invisible vein can be sought with the minimum of trauma. An additional advantage of the small needle is that the injection must be made at a moderately slow rate, which is a "safety valve" in certain cases—e.g., pento:hal and uroselectan.

Effects of Sweets on Teeth

Dr. ALEXANDER LIVINGSTON, L.D.S. (Southampton), writes: With further reference to Dr. H. E. Magee's Milroy lecture, and Miss Dorothy M. Richardson's note (June 29, p. 1010): for some four years, 1936-9 (when chocolate became unobtainable in quantity), I always ate chocolate before going to sleep, that is, in bed, and left a little undissolved against my pendant right upper molars. By 1940 the third molar had developed a cheek-surface cavity, and was extracted as unsavable. Three weeks ago the second molar broke down while eating bread-and-butter, with crust admittedly. It, too, is doomed to extraction; it is a typical, slowly progressing, and absolutely "hollow" tooth.

A Possible Sanatorium

Dr. E. VIPONT BROWN (Carnforth) writes: After many years I have at last heard from a dear friend of mine, Dr. Mitterstiller, Hotting, Sonnerstr., 4, Innsbruck. In his letter he says: "In the neighbourhood of Innsbruck, about 1,400 m. high up in the mountains, there has been erected a large building for training the soldiers in skiing. Naturally it is not finished and practically ownerless. The place would be suitable for a sanatorium like that of Rollier's in Leysin in Switzerland. Do you think that an association of medical men in England would be interested in erecting there such a sanatorium for surgical tuberculosis?" I am now far too old (83) to take any active interest in such a scheme, but I thought it might be well to publish the suggestion in your columns. Some who are acquainted with the glorious mountains round Innsbruck may feel attracted to the idea.

Health Service Bill

Dr. J. A. Balck-Foote (Andover) writes: I regret that in my letter (July 27, p. 138) I used the word "affected" in para. 1 twice, leading to possible misunderstanding. On the second occasion it should be replaced by "weakened."

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 3 1946

BRITISH MEDICAL ASSOCIATION ANNUAL REPRESENTATIVE MEETING, LONDON, 1946

The Annual Representative Meeting opened in the Great Hall of M.A. House, Tavistock Square, London, on Tuesday, July 23, and was continued on succeeding days. Dr. J. B. MILLER, shopbriggs, Lanarkshire, presided, with Dr. E. A. Gregg, London, in the vice-chair. They were supported by Mr. H. S. Souttar, President, Dr. H. Guy Dain, Chairman of Council, Mr. J. W. Bone, Treasurer, and the officials of the Association. The number of representatives attending was about 300, including 20 from overseas constituencies and apart from members of Council who were not acting as representatives. About 200 motions and amendments were on the agenda. It was agreed that those relating to the National Health Service should be taken as the first business on the second day.

FIRST DAY

Tuesday, July 23

The meeting assembled at 2 p.m., following a Council meeting in the morning.

The late Sir Kaye Le Fleming

The CHAIRMAN, in opening the meeting, said: We have to mourn the sudden death of Sir Kaye Le Fleming. This is not an occasion on which to dilate on his many services to the Association. Suffice it to say that he was Chairman of the Panel Conference for three years, Chairman of the Representative Body for three years, and Chairman of Council for five years. During all that period he was busily engaged in the active practice of his profession in a country district, involving a strain which must have affected even his powerful physique. He was dignified in his bearing, impartial in his judgments, and wise in his counsel. He well qualifies to join the great line of past leaders of the profession, and his name will go down as one of the greatest statesmen the B.M.A. has ever had. The meeting will wish to express its grief at his passing, and to have its sympathy conveyed to his widow.

The members of the Representative Body stood for a few moments in silence.

Greetings from South Africa

Prof. J. F. BROCK, Professor of Medicine, University of Cape Town, and Chairman of the Negotiating Committee of the Medical Association of South Africa, brought the greetings of that Association. He said that the South African Association had recently spread its wings and flown out of the nest, but it was not proposing to fly very far away. As in this country so in South Africa, they were facing revolutionary changes, but in South Africa they had been more fortunate in the way the Government had introduced its legislation. The Government had taken one of the members of the Association and made him Chairman of the Health Services Commission, and that Commission having produced a report to which the majority of the medical members subscribed, the Government accepted the report and proceeded to make the chairman the Minister for Health. (Laughter and applause.) They had therefore in South Africa a Minister for Health who was a member of their own profession and Association, and they had been very fortunate in building up by that means a real spirit of team work in the introduction of the new health services scheme. They had their difficulties with the provincial administrations, but so far their negotiations with the Government had been very happy indeed. (Applause.)

Agenda of Representative Meetings

Following upon a matter raised by the Winchester Division at the Special Representative Meeting in May concerning the procedure of the Representative Body, the Agenda Committee presented a report examining the possibilities of reducing the number of motions and amendments so as to ensure that the whole of the agenda received adequate consideration. One method suggested was to make use of larger local groupings of the Association as a filter between the Divisions and the Central Agenda Committee, so that Divisions would be required to refer their motions in the first instance to Branch Councils or grouped Branch Councils. It was considered that in practice this would prove rather cumbersome and would require considerable time to function. Another method would be for the Agenda Committee to prepare appropriate omnibus motions to cover the intention of similar motions submitted by several Divisions. These omnibus motions, however, would have to be conveyed to the Divisions concerned, and any dissenting Division would have the right of submitting an amendment, so that the method would be protracted and possibly would result in no saving. To give the Agenda Committee absolute discretion to compile omnibus resolutions and exclude those of the Divisions concerned without reference to them was considered too drastic and dictatorial. The committee recommended that no action be taken at present to modify the procedure, but that the plan of starring certain resolutions should be given a further trial. A further recommendation was that two members elected by the Representative Body be added to the Agenda Committee.

Dr. W. D. KEYWORTH (Winchester) and Mr. ERIC STEELER (Marylebone), whose Divisions had raised the question at a previous meeting, expressed themselves satisfied. Dr. C. E. DAWSON (Derby) said that it did not seem as if much progress had been made; the congestion of business would continue. The only remedy was some curtailment of the length of speeches.

The recommendations of the Agenda Committee were agreed to.

ANNUAL REPORT OF COUNCIL

Preliminary

The meeting then turned to the examination of the Annual and Supplementary Reports of Council, published in the *Supplements* of April 20 and June 22.

The CHAIRMAN OF COUNCIL (Dr. Dain), who was received with cheers, said that their old friend and highly valued servant of the Association, Mr. H. S. Souttar, had found himself unable to accept nomination for another year as President, and they could not let an opportunity pass without an expression from the Representative Body of its friendship and esteem for him personally and its appreciation of his services. (Loud applause.)

Dr. Dain went on to say that the Association was getting its staff into working order. The Council had appointed two new Assistant Secretaries, Dr. Claxton and Lieut.-Col. Stevenson, and a new Scottish Secretary, Dr. Walker, each of whom he introduced to the meeting.

Another matter which came into this part of the Council's report concerned the work of the Medical Curriculum Committee under Prof. Cohen of Liverpool. He thought its report

would be found so valuable when it appeared that it should properly be labelled "Report on Medical Education." It would be one of the most useful documents ever issued on the education of the medical practitioner.

On the question of international relations the Council had taken the view that the Association should give a lead in bringing together the medical associations of the various countries, and an international conference would be held in that building in September with a view to promoting an international body for the exchange of information, the promotion of closer ties, and the encouragement of better international relations generally. The Council that morning had also agreed to set aside the sum of £1,000 for the purpose of enabling B.M.A. lecturers—some of the best-known experts in their subjects—to visit Continental countries and give lectures to their medical colleagues in those countries.

President, 1946-7

A recommendation of Council—

That Sir Hugh Lett, Bart, C.B.E., D.C.L., F.R.C.S., be elected President of the Association, 1946-47—

was carried unanimously. It was stated that Sir Hugh Lett would be introduced to the meeting on the following day.

"A Charter for Health"

Dr. NOY SCOTT (Plymouth), while commending the excellence of a *Charter for Health*, issued by the Association, complained of its high price (6s.), which was likely to interfere with the wide publication which it deserved. The Association could well afford to subsidize this book, and so ensure its circulation at a considerably reduced price.

Dr. R. W. COCKSHUT (Hendon) said that 5,000 were printed, and all had not been sold. To subsidize a publication like this might involve a large expense, but the Council had had it in mind, if it was successful, to publish it in something like a "Penguin" edition.

The suggestion from Plymouth was referred to Council.

Assistance for Ex-Service Practitioners

Dr. J. A. GORSKY (Westminster and Holborn) moved:

That this meeting considers that steps should be taken to cause the appropriate authority to be empowered to give some assistance to practitioners leaving the Services to acquire premises which may be used as surgeries.

Many practitioners had lost their surgeries owing to enemy action, and the burden on the practitioner returning to his practice must often be very heavy.

Dr. S. LAURIE SMITH (Blackpool) said that if the Association was going to give the ex-Service men the opportunities they ought to have, this motion should be supported.

The CHAIRMAN OF COUNCIL said that there were no special privileges for doctors in the matter of housing, but the Association did help as far as it could in any individual cases which were brought to its notice. The matter was constantly under consideration, and he was prepared on behalf of the Council to accept the motion.

he motion was referred to Council.

General Practice

Dr. S. WAND (Chairman of the General Practice Committee), in presenting this section of the report, said that his committee had dealt with many matters referred to it by the last A.R.M. The capitation fee for treatment of firemen had been settled for the time being; the remuneration of surgeons under the Factories Acts had been taken up, and they were proposing to present certain rates to the Government department concerned; civilian practitioners' fees had been raised; the resolution of last year on night calls had enabled them to get some improvement in the hours for which the night fee was payable, and evidence had been given to the appropriate body on fees for medical witnesses. During the last session joint committees with the pharmacists and with the nurses had been working, and the Ship Surgeons Subcommittee had been restarted. The Industrial Medical Officers Subcommittee had become a fully established committee of the Association. It had done most admirable work during the past year under the chairmanship of Dr. Vaughan Jones.

Fees for Life Insurance Examinations

Dr. WAND said that there was a recommendation in his report before the meeting that the agreement reached with the Offices Association in 1919 with regard to fees for medical examination for life assurance should be terminated. That recommendation was tabled they had been in conversation with the Life Offices Association, and negotiations were proceeding; he hoped it would be possible to report to next A.R.M. a satisfactory increase in the fees payable, as a measure of standardization. To pass the recommendation at the moment would be to leave a gap, and accordingly proposed to move it in the form that the Council be empowered to terminate the agreement at the appropriate time when it was possible to negotiate a new agreement.

Dr. HUNTER (Plymouth) said that his Division had put down an amendment to a recommendation which he understood Dr. Wand would not now move, but which suggested a smaller fee for a "modified examination." He felt that "modified examination" was very hard to define, if it existed. When a patient went into the consulting-room it was difficult to lay down any conditions which did not involve a thorough examination. He hoped that the committee would bear this in mind in its negotiations with the Life Offices, that if a modified fee was accepted it would be only for a report which did not involve examination, but only on previous knowledge of the patient.

Dr. WAND said that in discussions with the Life Offices Association he found that they used different types of tables for different types of insurance—full actuarial tables for higher amounts and different tables for the smaller amounts and for these different tables they required different kinds of information.

The motion empowering the Council to terminate the agreement at an appropriate time was carried.

Dr. P. INWALD (City of London) moved:

That this meeting recommends that when a doctor is requested by an insurance company or a solicitor to be present at the examination of his patient by another doctor for the purpose of assessing a claim arising out of the patient's injury or illness the fee payable should be not less than £2 2s.

Dr. WAND said that he was prepared to accept this as a reference to Council so that the position might be explored and any necessary action taken.

This course was agreed to.

Private Practice under a 100% National Health Service

Dr. WAND next moved formally on behalf of the Council that the conclusions reached by the Council on the safeguarding of private practice under a 100% National Health Service be approved. The conclusions were:

1. That the principle of collective responsibility obtaining under the present N.H.S. scheme should not hold in the new service.

2. A general practitioner who contracts to give service under the National Health Service should be entitled as a right to accept patients as private patients. He should be entitled to treat privately any person who is not on his own list or that of any partner or assistant, whether on the list of another doctor or not. Where a practitioner has accepted a patient as a public service patient he shall be precluded from charging fees for any service he renders to that patient as a general practitioner.

3. A practitioner should be free to give such certificates, prescriptions, orders, or reports to his private patients as would secure for them any of the statutory benefits under the National Health Service.

4. Except in an emergency a general practitioner should not be required to treat as a public service patient any person: (a) not on his list; (b) who resides outside the area of his practice (as agreed by the local executive council).

5. A general practitioner should have the right to refuse to accept any person as a public service patient without giving reasons. Similarly, a patient should have the right, without giving reasons, to ask for the withdrawal of his name from a practitioner's list. A general practitioner should be entitled to ask for the removal of a patient from his list, without giving reasons, but should give or continue treatment for a limited period until the patient is accepted by or is allocated to another practitioner. The interval for change of doctor (other than by consent) should be as short as possible.

6. Where a public service patient on a doctor's list desires to be treated privately by that doctor, the patient should be required, before being accepted as a private patient, to give due notice of the withdrawal of his name from the doctor's list.

7. A member of a partnership who elects to remain outside the service should not treat as a private patient any patient on the list of another partner in the firm. He should be regarded as

leputy in these circumstances; but this should not preclude him from treating as private patients those seeking his advice as a consultant or specialist.

8. Public general practice should be held to mean the treatment by the practitioner of persons on his list at the place appointed or the purpose—i.e., the health centre, the doctor's surgery, or the patient's home—but where public practice is conducted from the health centre private practice should be conducted at some place other than the health centre.

9. A patient should not be required to give official notification of his intention to obtain his general practitioner service privately. The doctor may obtain for his own use such evidence as he thinks desirable.

Dr. HOWIE WOOD (Isle of Wight) moved an amendment to delete the words in para. 2 "of any partner or" and substitute the words "of his," thus making a practitioner entitled to treat privately a patient who was on his partner's list. He said that in his area they had not, generally speaking, combined practices which were taken sometimes by one member of the partnership and sometimes by another. Their practices were separate practices, and when a patient who was on the list of one member of the partnership wished to consult another partner, or own doctor being available at the time, a fee was charged to that patient by the partner whom she consulted. There was no question of this being done when the second practitioner was acting as deputy for his partner. He wished to limit the practice to cases in which the patient's own doctor was available, but the patient for her own reasons wished to consult the other partner. Under the recommendation as Dr. Wand had moved it it appeared that a certain amount of private work otherwise available to doctors in partnership would be lost to them.

Dr. WAND said that in considering any scheme for private practice they must have in mind something that would work and would be fair and honourable. Was the Isle of Wight suggestion honourable?

Dr. HOWIE WOOD replied that it seemed to him, listening to Dr. Wand, that the only way to avert the loss to private practice would be dissolution of the partnership. If the practitioners were not in partnership no one would suggest that there was anything dishonourable in charging a fee to a patient who was not on the list of the partner.

The Isle of Wight amendment was lost.

Dr. C. MACKIE (Worcester) moved to amend para. 4 of the recommendation by making it read: "Except in an emergency or while the patient is temporarily resident away from home a general practitioner should not be required to treat," etc., and to make the paragraph end with the words "as agreed with the local executive council," instead of "by the local executive council." They expected the Executive Council to discuss with every individual practitioner questions relating to the area of his practice, the doctor specifying the district he would practise in, as he did to-day under National Health Insurance.

Dr. WAND said it was evident that temporary residents would have to be dealt with under the Act and not under regulations. So far as the second part of the motion was concerned he was prepared to accept it. He thought there must be agreement with to get agreement by.

The first part of the Worcester amendment was lost, and the second part agreed to.

Private Patients and Health Centres

Dr. MACKIE further moved to amend para. 8 to provide that it should be open to a practitioner to conduct private practice at a Health Centre or elsewhere at his own discretion. His Division put forward this amendment in a spirit of inquiry. In his Division there were many rural and semirural practices, and in many parts of the county a practice or partnership had to do all kinds of jobs—midwifery, surgery, public health work—and to doctor the squire as well as the ploughman. There could be no question of turning down work because it was troublesome, dirty, or unprofitable. Everything had to be tackled—gipsies, hop-pickers, private patients—and the National Health Service practice would have to be tackled also. When his Division discussed the Council's report it occurred to them with considerable dismay that they would be required to see their public patients at the Health Centre and their private patients at home, and how could they possibly find time to do double surgery duty? Was it possible to do three or four

surgeries and then embark on visits round fifty miles of countryside? They came to the conclusion that there would be a gross and uncalled-for waste of time which would interfere with the giving of their best to public and private patients alike. What was the opinion of the meeting about two separate establishments? Many a young man, faced with the demand for two establishments for his practice, would not be encouraged to practise privately. Why should not private patients have the technical facilities of the Health Centre and if necessary pay for them? What was good enough for public patients was good enough for private, and vice versa.

Dr. D. J. MORRISON (Edinburgh) spoke to the same effect. He did not see why a private patient should be denied the benefit of going to the Health Centre.

Dr. WAND said that he had a good deal of sympathy with this amendment. After all, if Health Centres were set up it seemed unreasonable to expect the private patient to put up with something less in the way of equipment than the public patient. But was it going to be possible for the private and the public patient to attend the Health Centre in the same circumstances, one paying and the other not, when 100% of the population were entitled to the service? Nevertheless, the whole problem was in the melting-pot, and he, frankly, wanted to see a good deal more discussion on this point. If the meeting was willing he would take the matter back to his committee, and they would have another look at it.

The amendment was agreed to as a reference to Council.

The Private Patient's Drugs and Appliances

Dr. R. W. COCKSHUT (Hendon) moved:

That the patient who elects to obtain medical advice privately shall not be required to pay for drugs and appliances.

The Minister had promised on many occasions that people would be able to take this service in whole or in part, but he had refused to separate the medical from the pharmaceutical service. In the Bill as amended in committee (Clause 38) it was laid down that—

"It shall be the duty of every Executive Council . . . to make as respects their area arrangements for the supply as from the appointed day, whether at a health centre or otherwise, of proper and sufficient drugs and medicines and prescribed appliances to all persons in the area who are receiving general medical services."

This meant that patients would be able to get medicine and appliances free only if they were receiving service as public patients. Every private patient would be required to pay for his drugs and appliances—his penicillin, his insulin, his artificial limbs, and so on. The Minister admitted that a man might wish to have another opinion and might go to another doctor in the service and pay him for that consultation, but he would expect that patient then to transfer to the list of the doctor whom he had consulted. He had further said that only those patients who did not come on to the list of any doctor might be treated as private patients. If the patient, in addition to paying privately for advice, had also to pay for the expensive things used to-day, private practice would disappear. His impression was that the Minister did not intend that there should be any private practice.

Mr. C. E. BEARE (Reigate) supported the amendment.

Dr. WAND said that Dr. Cockshut was evidently aware of the administrative difficulties. If the meeting regarded the difficulties as insuperable they would vote against this amendment; if not insuperable they would vote for it.

The amendment was carried. This concluded the discussion on the Council's concrete proposals for safeguarding private general practice, and these, as amended, were approved.

The Maintenance of Private Practice

Dr. H. S. PASMORE (Kensington) moved to request the Council to give urgent consideration to the methods by which private practice may be maintained in future. It was the obvious intention of the Minister to suppress private practice as far as possible. He quoted his speech on the second reading on April 30, when he said: "The whole purpose of the scheme is to provide free treatment with no fee-paying at all." They were all anxious to know how private practice could be maintained in the future. At the moment they had free State education, but private schools were flourishing. The Labour Government, however, would not allow such a thing to repeat itself in the planning of

the health service. One way in which private practice would have a better chance of being maintained would be the taking of more vigorous steps to reinstate demobilized practitioners in practice and to help young doctors into practice, so that these people would not be "on the market," so to speak, when the scheme came into force in 1948.

The motion was carried.

Mr. C. E. BEARE (Reigate) moved:

That, in agreement with the decisions reached at the S.R.M. in May, 1946, this meeting considers that it is essential that the financial and administrative arrangements should be such that neither doctor nor patient is penalized if he chooses to remain outside the service.

One thing of which he was very much afraid was that if a man stayed outside he would not be admitted to look after his patient in hospital.

Dr. J. B. W. ROWE (Harrow), in supporting the motion, said that if patients were not given grants in aid they were likely to be penalized.

The motion was carried.

Supplementary Clothing Coupons

Dr. ROWE (Harrow) moved:

That the Council be instructed to press the Board of Trade to take such action as will improve the supply of operating gowns, surgeons' coats, and overalls, so that an issue of supplementary clothing coupons can be made with which to obtain these articles.

His Division felt that the Council had approached this problem from the wrong end. Further steps should be taken. The Board of Trade should be pressed to have these things made. If this state of affairs went on they would soon be operating in frock coats and going back to the pre-Listerian era.

Dr. WAND said he understood that some form of announcement was to be made by the Ministry in the near future on the question of surgeons' gowns. The Council was doing what it could to press on with this matter.

Dr. W. D. STEEL (Bromsgrove) thought that it would strengthen the hands of the Council to have a vote at that meeting. The profession was finding things very difficult. What about the danger to the woman in labour if the obstetrician—a general practitioner, he hoped—was not able to provide himself with a sterilized gown?

The motion was carried unanimously.

Doctors' Cars

Dr. JOHN YOUNG (Lothians) moved that the Minister of War Transport be approached with a view to enabling doctors to receive priority in the delivery of new cars. The majority of them were suffering from delay in getting needed replacements.

Dr. WAND said that the Ministry of War Transport had nothing now to do with the distribution of cars: it was a matter entirely in the hands of distributors, some of whom were playing the game, and so were some of the agents; and at the head office they were doing all they possibly could. But it was useless to pass the resolution.

The resolution was withdrawn.

Scale of Fees for Admiralty Surgeons

Dr. H. F. HISCOCKS (South Essex) moved:

That the Council be asked to take action in order that the scale of fees paid to Admiralty surgeons and agents be revised in order to conform with the revised fees now paid by the Service Departments to civilian medical practitioners in accordance with para. 42 of Council's Report.

This motion affected a relatively small number of practitioners, and his Division felt that the position of Admiralty surgeons and agents ran the risk of being overlooked altogether. Fees had been raised in most departments of medical practice, but Admiralty surgeons and agents still got only 3s. for a consultation (including medicine), 4s. 3d. for a visit (also including any treatment required), while for the responsible task of visiting a sailor in his own home and reporting to the Lords Commissioners of the Admiralty on his condition the agent was rewarded with 3s. 6d. This was a disgrace to the profession and a state of affairs which should not be allowed to continue a day longer than was necessary. A letter was sent to the Medical Director-General on Feb. 25, and a little later a reply was received to the effect that the question of modifying the

fees of Admiralty surgeons and agents was still under consideration, and it was hoped that a decision would be forthcoming at an early date. That hope had not been fulfilled. The in this respect was justifying its title, "the silent Service."

Dr. WAND said that the Admiralty had been told about twice recently, and there had been no reply. The Council would continue to act energetically in this matter. He thought this was the only field with which the General Practice Committee had had to deal in which it had not been able to any increase so far. The explanation was the tardiness of Government Departments.

The motion was carried.

Telephone Facilities for Doctors

Dr. P. N. CUTNER (Westminster and Holborn) urged representations should be made to the Postmaster-General that the telephone service should provide facilities for exchange for taking messages during such times as a doctor might notify that his telephone would be unattended. Was a telephone service be possible for doctors only? Dr. CARTER (Bournemouth) said that some such arrangement would be of great value not only to doctors but to their patients. Dr. WAND said that a bureau of this kind was established in Birmingham before the war and was very efficient. Was the intention to extend the service as and when considered permitted.

The motion was carried.

A motion by Hendon asking the Council to take steps to secure an increase of the visiting fee and the abolition of the overriding quarterly maximum paid by the Post Office to medical officers for attendance on postal employees living in the district of their employment was accepted.

The Working of the Coroners Acts

Dr. R. FORBES (Hendon) moved:

That the Council be invited to review and submit a report on the working of the Coroners Acts since their introduction, to draw special attention to the difficulties attendant upon pathological examinations, fees payable to medical practitioners as witnesses, and other difficulties experienced by the profession in carrying out the statutory and other directions of the coroner.

Hendon was of opinion that the time was ripe for a consideration of the working of the Coroners Acts. It was certain amendments so that the relationships between medical practitioners and coroners might be improved. The official coroner carried many important and responsible duties which brought him into contact with members of the public at serious and critical moments. A change of procedure would be desirable whereby the coroner would be restricted largely to his primary duty of finding the cause of death, and prevented from embarking, as he often did, upon criticism of the treatment given to the deceased before his death. Doctors had been the subject of adverse criticism in the coroner's court on matters which seemed wholly irrelevant to a decision as to the cause of death. Many practitioners were asked to provide reports for coroners without being adequately prepared for such reports. Post-mortem examinations were frequently conducted without the practitioner who was or might be concerned being informed that the examination was taking place. Wider facilities should be made available to pathologists for the conduct of their work. The conditions under which pathologists were required to carry out their work were appalling and the fees unsatisfactory. The fees payable for provision of a medical report and for attendance at a coroner's court as a witness were defined in the Act itself, and could be changed only by the introduction of a new measure. Practitioners who worked in hospitals and found themselves subject to extraneous directions by the coroner, who sought to lay down certain rules which he required to have observed concerning the death of people some days after admission to hospital or after operation, were deserving of sympathy.

Dr. D. M. THOMSON (Dartford) urged that general practitioners should be allowed to carry out their own post-mortem work. It should not be done by some one pathologist appointed by the coroner.

Dr. W. B. A. LEWIS (Shropshire) said that as a general practitioner part-time coroner he had much sympathy with the motion. In his experience he had asked general practitioners to perform post-mortem examinations; some had not liked

l these were allowed to refuse. On one occasion he asked general practitioner to carry out a post-mortem examination, and he reported that he could not find the cause of death, and asked the speaker to make an examination, which he did, and could not find out the cause of death either. It seemed ridiculous to expect this very specialized branch of work to be carried out by the general practitioner. There were cases in which the cause of death was so obscure that it was nonsense to expect the general practitioner to express an opinion. It might not be generally known that a practitioner might claim a fee of half a guinea if, at the coroner's request, he gave an opinion as to the cause of death. The fee for a post-mortem was two guineas, and with attendance at inquest three guineas, with mileage. He agreed that this was quite inadequate remuneration for a trained pathologist. He did not believe that an inquiry instituted by the Council would lead to any result. The position could be altered only by legislation.

In 1936 there was an inquiry into the matter, but no legislation followed, and the coroner was left *in statu quo*.

Dr. WAND said that conditions varied in different parts of the country. He would like to accept the Hendon motion on condition that Dr. Forbes, who knew more about the problem than most people, wrote a memorandum for the guidance of the Council.

Dr. FORBES said that it was true that conditions did vary, and there were coroners and coroners; nevertheless, the time had come ripe for a procedure of this kind to be taken.

The motion was carried.

SPECIAL PRACTICE

Mr. A. H. BURGESS, chairman of the Special Practice Committee, introduced the sections of the report under this heading.

Dr. H. M. BIRD (West Suffolk), on the question of the status of the Consultants and Specialists Group Committee, moved that local meetings of consultant and specialist groups should be open to all such consultants and specialists, whether whole or part-time. It had been the practice in the past in certain local meetings to debar consultants and specialists who were also general practitioners from attending.

Mr. BURGESS said that the practice varied. In Manchester all consultants and specialists were invited to the meeting, though only whole-time consultants were entitled to vote. There were now some ten Group Committees in the Association, each representing some special type of practice, and the eleventh was in process of formation. Recently the Consultants and Specialists Group Committee resolved that those representing all types of consultant and specialist practice should be granted the right of approach to the Council direct rather than indirectly through the Special Practice Committee, and the Council's view was that the best way of dealing with the situation was to constitute a new committee and make it a standing committee.

The West Suffolk motion was carried as a reference to Council.

Part-time Consultants and Specialists

Dr. HOWIE WOOD said that the Isle of Wight, whilst approving para. 51 of the report, relating to part-time consultants and specialists, moved a resolution requesting the Council to take the action which was urged by the last Annual Representative Meeting in order to allay the present widespread apprehension—namely, to inform part-time consultants and specialists on hospital staffs that steps were being taken to safeguard their position and future employment. He apologized for returning to this thorny subject. He thanked the Council for the well-documented statement which had been furnished in the report, but he wished to remind the Council that the Representative Body had expressed the view that the position and future employment of part-time consultants and specialists on hospital staffs should be safeguarded, and that the Council should take measures to achieve this result. There was representation of part-time specialists, which was a good thing, but the Council was also asked to furnish a statement of what was being done at the present time to safeguard the interests of these people. The Council seemed to shy from this position like a startled horse.

Mr. A. S. GOUGH (West Hertfordshire) said that the Council had taken this matter quite seriously. The new Group Committee gave part-time consultants a definite position. In future

they all stood as one group. The fact that they were part-time meant no differentiation in the eyes of the committee. The part-time consultant and specialist had not been defined, and could not be, but they were asked to elect him in their areas to represent his category.

Mr. C. E. BEARE (Reigate), in supporting the motion, said that the tendency of the National Health Service would be to divide them into common-or-garden general practitioners—general sorters—and specialists. It was important to encourage the part-time specialist.

Dr. H. W. BOWYER (Bolton) said that in his town there were 14 honorary part-time specialists—general practitioners—out of a total personnel of 42, and these had 60,000 patients out of a population of 170,000. More than a third of the members of the profession and more than a third of the population were affected by this position. These honoraries wanted to know whether they were eligible for compensation for their general practice if they elected at hospital the consultant side.

Dr. W. D. STEEL (Worcester and Bromsgrove) said that in his town they were anxious that the interests of the part-time consultant should be properly watched. How were the five part-time consultants and specialists to be chosen for the Consultants and Specialists Committee out of the enormous number of such persons?

The CHAIRMAN OF COUNCIL said that part-time consultants were being given representation on the Consultants and Specialists Committee. But what Dr. Howie Wood was really asking was their position in the new service, and that was what no one could say at the moment. The terms and conditions in the new service were not known. The Council understood the position of the part-time men and was prepared to look after it properly when the question arose.

Mr. BURGESS said that every suggestion concerning the part-time men had received consideration and, if approved, had been passed on to the Council.

Dr. HOWIE WOOD thanked the Chairman of Council for his statement. There was widespread apprehension that the Government intended to abolish the part-time consultant, and that they would be given the option of either becoming whole-time consultants or general practitioners. His motion implied no reflection on the Council.

The Isle of Wight motion was carried.

Consultants and Specialists and the National Health Service

Dr. R. S. P. BEGG (Harrow) drew attention to one of the proposed safeguards for consultants and specialists which the Negotiating Committee had been asked to consider—namely, "Consultants should be available under the scheme for domiciliary work only within the district they serve"—and proposed to add, "unless the consultant himself wishes to call in another consultant from outside the district." It should be the privilege of the visiting consultant to call in any other consultant, whether outside his district or not, for the benefit of the patient.

Mr. BURGESS said that he was willing to accept as a reference to Council a motion in the sense that Harrow wanted. The decision as to the boundaries of areas did not remain with them, it was a matter of regulation.

The Harrow motion was carried as a reference to Council.

Free Choice of Consultant

Dr. W. D. STEEL (Worcester and Bromsgrove) proposed to add certain words to another of these "safeguarding" clauses—namely, the one which said there should be freedom of choice of consultant within prescribed limits. The words he proposed to add were, "but in the case of ambulant or movable patients there should be complete freedom of choice of consultant." At present a general practitioner had the right to refer his patient to any consultant he wished. Under the new arrangement it would appear that the general practitioner would be tied to the consultants available in the region where the patient lived. The patient might desire for various reasons to have a consultation with a specialist outside the region, or he might move his residence while under treatment. It should be possible for regulations to be made that where the patient could be moved he should have free choice of consultant.

Dr. G. P. WILLIAMS (Cardarvon and Anglesey) said that another aspect arose in what he might call under-specialized areas such as his own in North Wales. In a sparsely populated

district there was special need for defending the freedom to send the patient outside the district. Wales was likely to become one region, and it was feared in North Wales that the result might be to cut them off from their fruitful contact with Liverpool. Obviously, for geographical reasons, they could not send their patients from North Wales to South. Mr. Bevan had said that a plan would be worked out for Wales which would command universal approval. "But my fellow-countryman's idea of universal approval may not be ours."

Dr. R. G. GORDON (Bath) supported the motion on behalf of spas and health resorts where people were sent for special treatment.

Mr. BURGESS accepted this on behalf of Council for further consideration by the Negotiating Committee. He thought that if it could be arranged it would be a very good thing.

The motion was carried.

Examination of Pensioners referred to Specialists

Dr. J. WILKIE (Lancaster) moved the reference back of the first part of para. 53 of the Annual Report, relating to the approval of a revised scale of fees to be paid by the Ministry of Pensions for cases referred to specialists. He had never been able to understand on what basis sessional payments were assessed. Was it on a time or a case basis? What was a whole session and what a part session? He could not understand the differentiation in payments. If payment was on an item basis, each comparable item must be paid at the same rate. In recent years there had been a deplorable tendency to pay 10s. 6d. for one examination and two guineas for eight. That happened in the case of examinations for the Ministry of Labour and for fire watching. If a tapering scale was approved it would be a dangerous precedent because Mr. Bevan would be led to believe that they were ready to accept it for the general practitioner.

Mr. BURGESS said that these were not sessional fees but fees per case; but he was willing to take the passage back for reconsideration.

This was agreed to.

The "Open Door"

Dr. H. M. BIRD (West Suffolk), with reference to para. 57 of the Annual Report, concerning access to ancillary departments of hospitals, moved:

That experience having shown that the advantage of the policy of the "open door" outweighs the disadvantages, it should be adopted as a uniform system throughout the country.

The principle of giving full facilities for pathological and radiological investigations and for services like physiotherapy to every general practitioner in the country without the intermediary of the out-patient department was very important. This method of the "open door" was adopted in West Suffolk 25 years ago, and they had had no reason to regret the decision. It had given the general practitioner an opportunity of treating his cases intelligently. He had been able, at his own direct request, to get any investigations he wanted done. It had saved the out-patient department from being flooded out, and it saved the patient a long and tedious wait.

r. TALBOT ROGERS (Bromley) said that in Kent during the few years they had had a committee which combined representatives of the voluntary hospitals and of the county council for the purpose of planning a hospital service. In its report it advocated an "open door" policy. A pathologist of a voluntary hospital objected to one observation in the report, and said that in his view only certain simple investigations, such as blood count or sedimentation rate, should be available to general practitioners, and that pathological investigations in general should be carried out by those familiar with the indications for their employment and with the interpretation of their clinical significance. He was happy to say that that opinion was rejected by the committee, and rejected most emphatically by the medical officer of health, whose experience was that there was no abuse of the facilities by general practitioners.

Dr. W. GUNN (Greenwich and Deptford) did not consider the "open door" policy wise or safe. The increasing flood of work it would bring to the ancillary departments would lead to a situation where opinions would be given by technicians, not checked by specialists at all. He did not doubt the

competence of the general practitioner to interpret the report but he was afraid he might not get the proper facts.

Dr. F. M. ROSE (Preston) said that there was a tendency for specialists to be very jealous of their own particular domain. He came from an area where these facilities were fully available and were used wisely. There had been no breakdown and the matter had worked very satisfactorily. But he knew of another area in Lancashire—Stockport—where these facilities were not available and the doctors there had many difficulties.

Dr. W. E. DORNAN (Sheffield) said that for 20 years the "open door" had been available in the radiological department to any practitioner in his city. This was not abused by the general practitioners concerned. In Sheffield also pathological facilities and physiotherapy arrangements were available.

Dr. J. A. IRELAND (Shropshire) said that he could never accept the implication that the general practitioner was unfit to send anyone to the special department unless the patient passed through the "usual channels." The "open door" should be strongly supported.

Dr. R. O. EADES (East Suffolk) said that the mover of the amendment, his colleague of West Suffolk, and himself in East, were in areas where these facilities were available, and there had been no difficulties. The pathological services during the war were supplied by the E.M.S.

Dr. C. M. STEVENSON (Cambridge) said that the "open door" was not in operation in his town, and he was at a distinct disadvantage in endeavouring, for example, to get an x-ray report. Dr. H. J. COCHRAN (Burton-on-Trent) said that surely the technician would in nearly all cases perform the necessary tests. The interpretation of the test would be done by the doctor and the consultant. Dr. H. S. PASMORE (Kensington) thought that the "open door" method should be supported if only to save the time of their patients. Dr. HUNTER (Plymouth) said that the radiologist and the pathologist were consultants. They should not be regarded as "machine minders." The general practitioner was entitled to their opinion direct without the intermediary of hospital staff.

Mr. BURGESS explained that this question was brought to the Special Practice Committee by the Consultants and Specialists Group, who felt strongly that if the "open door" policy was widely adopted it would lead to such overcrowding of the special departments as to make them almost unworkable. The matter was referred to the Group Committees. The radiologists were equally divided; the pathologists were definitely in favour of the "open door." The matter was then referred to the Insurance Acts and General Practice Committees, and the "open door" was strongly favoured by both. The Council was advised to favour its adoption as an experiment. He was not prepared to recommend it as a uniform system throughout the country, though he thought it should be given a trial in certain areas.

The West Suffolk motion calling for the "open door" as a uniform system throughout the country was carried.

Post-mortem Facilities

Dr. I. G. INNES (East Yorkshire), on para. 129 of the report concerning inadequacy of facilities for post-mortem examinations in many parts of the country, asked the meeting to express disagreement with the principle that the decision as to who is a competent medical practitioner to perform post-mortem examinations should rest with the coroner. He said that morbid anatomy was not a subject which a general practitioner could be expected to carry with him throughout life. If a general practitioner had a certificate that he was qualified to do post-mortem examinations the coroner should use him, but in general the pathologist was the proper person. The choice of doctor to carry out post-mortem examinations should not rest with coroners, at any rate not with lay coroners.

Dr. W. B. A. LEWIS (Shropshire) agreed that the proper person to carry out a post-mortem examination was a qualified pathologist. Post-mortem facilities in many places were extremely poor. There were places where post-mortem examinations were made in which it would be unseemly to perform an examination on a diseased cow. Dr. R. FORBES (Hendon) pointed out that the East Yorkshire motion failed to state who should make the decision. Many would like to see a panel of suitable practitioners set up in particular areas.

ut to pass an amendment of this kind would be of no value. he coroner was an officer who stood intermediately between the public and the medical profession, and he seemed the most appropriate person to select the individual to carry out the post-mortem examination when the cause of death was unknown.

Dr. INNES said that the coroner should not use the ordinary practitioner but should choose one who was qualified by his knowledge of morbid anatomy.

It was moved, and agreed, to pass to the next business.

The meeting adjourned at 6 p.m.

SECOND DAY

Wednesday, July 24

The representatives reassembled at 10 a.m., with Dr. J. B. MILLER again in the chair.

ORGANIZATION

In introducing the report of Council under "Organization," Dr. J. A. PRIDHAM, chairman of the Organization Committee, spoke with great appreciation of the work of Dr. J. C. Matthews, its predecessor in the chair, which he had occupied for 13 years. Dr. Matthews was still a member of the committee, and they had the great benefit of his advice.

The membership of the Association continued to grow; in 1944 there were 52,507 subscribing members, which was a record. In 1911, that other year of crisis, the membership was 25,000.

Expenses of Representatives

Dr. VAUGHAN JONES (Leeds) moved that representatives, members of Council, and members of standing committees and other Council committees should be paid a subsistence allowance of one guinea a day or part of day on which they attended a meeting. This subject was reported on by Council in 1944, when it was decided against paying subsistence allowances, but in raising the matter again he suggested that the cost would not be prohibitive. The guinea would cover only expenses, not loss sustained by absence from practice, and it would not detract from the dignity of being a representative or member. Representatives attending the Panel Conference were paid subsistence.

Dr. P. W. MATHEW (Eastbourne) suggested that the payment would place a large strain on central funds, and that the expenses should be defrayed by the Divisions out of local funds by means of a levy. This had been done during the last two years by his Division. Dr. R. WILLAN (Oldham) supported the Leeds motion. Non-payment of a subsistence allowance reacted unfavourably on the availability of younger members of the profession as representatives. The Association prided itself on being a democratic body, but that was not entirely the feeling in the constituencies, where younger members felt themselves to be inadequately represented. He was against a local levy, because this was a matter affecting not the Divisions but the whole Association. Dr. J. GRIFFITH JONES (North Glamorgan and Brecknock) said that the ability to bear the expense of coming to town was often a criterion in the selection of representatives. Mr. C. E. BEARE (Reigate) thought it would be an unwise procedure for representatives to be subsidized by a central fund, but there might be a local fund on which it would be optional for representatives to draw.

Dr. PRIDHAM was in favour of a voluntary payment by Divisions. For 114 years the Association had been built up and its prestige increased as a result of the voluntary work done on its behalf. It was a pity if everybody wanted to receive financial recompense for everything they did. It was an honour and privilege to represent the Division, and it was not all give and no take, for it brought one in contact with one's fellows, and one went back with increased knowledge and possibly increased prestige.

A proposal to meet the expenses by a local levy was rejected, 84 voting in favour and 98 against.

The TREASURER (Dr. Bone) said that the effect of the Leeds motion would be to add £1,100 to the expenditure on a Representative Meeting, and the cost of Council and standing committees would be increased by £4,000. He reminded the meet-

ing of the heavy commitments of the Association in connexion with the National Health Service Bill, the post-war programme, the increase of staff, the schemes for regional development, and the establishment of a medical abstracting service. He suggested that the subject be referred to Council for examination and report by a committee with a view to an accurate estimate of cost.

The Treasurer's proposal to refer the matter to Council was adopted.

A motion by South-West Essex that all nominations of candidates for elections to seats on committees voted upon at the Representative Meeting should be published three weeks prior to the meeting so as to avoid a "blind vote" was lost. Dr. PRIDHAM suggested that this would favour the older men and prejudice the younger, who after making the acquaintance of the Representative Body were sometimes elected there and then on to committees.

Affiliation with South Africa

Dr. PRIDHAM brought forward for approval a scheme of affiliation with the Medical Association of South Africa. He reminded the meeting that at the request of the Federal Council in South Africa the Council in June, 1945, gave notice to terminate the agreement entered into in 1927 under which the Branches of the Association in South Africa acted as a corporate group of Branches within the Association. The problems in South Africa were different from those in some of the other Dominions, and it became obvious that the Medical Association of South Africa would have to move in this direction, and no exception was taken to it on the part of the B.M.A. The agreement came to an end on December 31, and from that date the Medical Association of South Africa achieved independence and self-government. A strong desire was expressed on the part of the Federal Council, however, for close relationship between the two bodies, to be effected by affiliation. The Council thereupon submitted to the Federal Council proposals for affiliation based to a large extent on the Canadian model, but introducing a proposal that there should be created a new class of membership under which membership of the Association affiliated to the B.M.A. would *ipso facto* constitute affiliation membership of the B.M.A. The affiliated member would be under no liability as regards subscriptions to the B.M.A.; he would be accorded the privileges of an ordinary member of the Association (other than the supply of the *British Medical Journal* and the right to vote at meetings of local units)—in other words, he would be entitled to attend meetings of local units of the B.M.A. in the area where he was temporarily resident, to attend the annual scientific meetings, to use the Association's house and library, and to have the help of the central staff in professional matters.

The Federal Council in South Africa had accepted in their entirety the Council's proposals for affiliation, and had suggested—and the Council here had agreed—that unattached members should not have the right to form a Branch of the B.M.A. within an area in which the Medical Association of South Africa operated, and, *vice versa*, that there should be some form of liaison between the two bodies, such as the nomination of a representative of the affiliated body to the Dominions Committee, and the appointment by the Central Council of an "observer" at meetings of the Federal Council in South Africa. The Federal Council in its letter had stated, "I can assure you that there is a keen desire to keep up a link with the 'parent body,' as your Association has been affectionately known, and the large number of our members who have retained their subscription to the *British Medical Journal* is a token of this desire." Dr. Pridham added that he was proud to be able to present the articles of affiliation between the friendly Medical Association in one of the great Dominions and the B.M.A.

Prof. J. F. BROCK of Cape Town, chairman of the Negotiating Committee in South Africa, said that he would convey to South Africa on his return the cordial spirit in which these proposals had been accepted. There was no question about the sincerity of the desire in South Africa for close affiliation with the B.M.A. The proposal for the "break-away" came in the early years of the war, but was generally disapproved at that stage in spite of the fact that it had to come sooner or

later. They did not wish it to take place during the war, and the issue was shelved until the war was over. It was the sincere desire of the Medical Association of South Africa to do all it could to create and maintain close links with the parent body. (Applause.)

The CHAIRMAN OF COUNCIL, as representing the practitioners in this country, welcomed the Medical Association of South Africa as a sister association. The B.M.A. had, or had had, Branches in every Dominion and Colony, and as some of these reached "dominion status" the parent was only too willing to see them achieve a friendly independence. He added that the B.M.A. had a membership in South Africa, before the "break-away," of 2,400. These ceased to be members on December 31, but 900 had taken out membership again in the B.M.A. while retaining, of course, membership of the Medical Association of South Africa. The membership figure of 52,500 just quoted by Dr. Pridham was computed after this loss of 2,400 and gain of 900. They welcomed South Africa as a grown-up daughter.

The recommendations of Council on this matter were approved.

Regional Organization

Dr. J. HALLAM (North Staffordshire) moved that in view of the possibility of the National Health Service Bill in its final form being unacceptable to the profession, the Council should take further steps towards decentralization of the Association by the provision of local organizers, either medical or lay, on a regional basis. He was casting no reflection on Headquarters, but it had been felt that Headquarters was overburdened with work. A committee set up some time ago to consider Association machinery had accepted the idea of decentralization and discussed ways and means, but little further progress could be made because in the existing situation the right men were not available. Since then the situation had changed materially, and his Division felt that the matter had become one of urgency. Whether they liked it or not, they had to face the fact that there was a considerable amount of apathy, and the apathetic sections of the profession were those, unfortunately, by whom they might have to stand or fall. Some attempt should be made to get these people into the fold as active members. A central organizer should be installed in each region. To expect the work to be done by the members of Council representing the various grouped areas was unreasonable—it was a full-time job.

Dr. A. V. RUSSELL (South Staffordshire) associated his Division with the motion. Mr. LAWRENCE ABEL (Marylebone) moved an amendment to omit the word "decentralization" and, instead of asking for medical or lay organizers, to ask for organizers, preferably medical. Mr. ERIC STEELER (Marylebone) seconded.

Dr. F. E. GOULD (Birmingham) pointed out that regionalization was already the policy of the Association and was under discussion by the Organization Committee. Dr. E. B. SMITH (Nottinghamshire) supported the proposal for regional secretaries. Dr. PRIDHAM said that a year ago a scheme was brought forward, but at the last moment was turned down, certain objections to it being pointed out. The matter was well in the mind of the Organization Committee and of the Council. A great deal could be done by group organization.

The SECRETARY (Dr. Charles Hill), at the request of the Chairman, made a statement on the present position at Headquarters. It was decided some time ago to increase the medical staff at Headquarters by two medical assistant secretaries, and with that increased staff to allot a certain proportion of the time of the whole of the six medical secretaries to regional activities. It would be possible from the end of September to begin the actual work. The plan proposed, which would be developed in the light of experience, was that the country should be divided into five regions, and that to each region an assistant secretary should be allocated. His or her task would be in the first instance, through conference with Division secretaries, to become acquainted with the secretaries' problems, to be available to address meetings in the Divisions, to stimulate inactive Divisions, and generally to be of service to Division secretaries and executives. Admittedly at the outset the position was one of compromise. The central staff would divide their time between the head office and the regions, but in the light of experience and within the limits of the available time

the services of the members of the central staff would be available to all the regions on a basis of allocation of one assistant secretary to each region. It was hoped to arrange from the outset for regular and quite lengthy visits by the respective secretaries to the regions under their care.

Dr. HALLAM said that his was a "gingering" resolution. It was no use having secretaries trained who would be of use in two years' time; the next eighteen months was the critical period. Nor were six secretaries and five regions sufficient; his Division's suggestion was ten. What was wanted was someone on the ground permanently.

The South Staffordshire motion was carried in the following form:

That in view of the possibility of the National Health Service Bill in its final form being unacceptable to the profession, this meeting is of opinion that the Council should take further steps to arrange for local organizers, preferably medical, on a regional basis.

THE NATIONAL HEALTH SERVICE BILL

At this point, by previous arrangement, the business under "National Health Service" was taken.

Dr. N. E. WATERFIELD proposed that for this business the Representative Body should go *in camera*. The motion, however, was resisted by the CHAIRMAN OF COUNCIL, who declared that there was nothing they had to say which could not be said in public and to the public.

By a very large majority it was decided that the debate should take place in public.

Chairman of Council's Statement

The CHAIRMAN OF COUNCIL prefaced the debate with a lengthy statement, which is printed in full in this week's *Journal* at page 168.

Discussion

Dr. D. C. BARRON (Sheffield) said that he agreed entirely with what the Chairman of Council had said. He thought it would not be quite fair to have a referendum of the whole of the members before some further guidance was given by the Representative Body. The feeling in his Division was that without such guidance they would be apt to get from many members no reply at all.

Dr. R. W. COCKSHUT (Hendon) said that if there were representatives in that assembly who did not agree with what the Chairman of Council had just said that was the time at which they should get up and say so. It was no use applauding Dr. Dain and at the same time harbouring reservations in their mind and saying something different in the Divisions. Mr. Bevan was a charming and brilliant man, strongly convinced concerning the ends he had in view, though perhaps not careful enough of the means whereby he gained them. He was no village tyrant, but a big man on a big errand, and if the profession was going to stand in his way, as the speaker hoped it would, it meant a very grave decision. Mr. Bevan would stick to his guns; they must stick to theirs.

Dr. J. C. ARTHUR (Gateshead) said that this matter looked as if it was going to come to a fight. In winning a fight one of the most important things was timing. Up to the present there had been no fight at all; only an exchange of diplomatic preliminaries. So far as the general practitioner was concerned, the time to fight was when he was required to sign on for this Service. What they had to concentrate on was being ready for the fight at the right time. He believed that practically the whole profession was agreed as to the rightness of the principles they had laid down, but a certain number of men would like to know more before committing themselves to an out-and-out fight. When this Bill became law the whole profession should be asked, "Do you wish us to go on and negotiate terms of service without prejudice to acceptance, or do you regard the whole thing as so unacceptable that nothing at all should be done about it?" If the latter view prevailed they must start very soon to marshal their forces. But if the majority of the profession desired that terms of service be negotiated, it would be possible to negotiate them and then present the profession with the complete picture and ask its decision.

Dr. S. F. L. DAHNE (Reading) said that the meeting should back Dr. Dain and the Council absolutely. The choice was a very simple one—between good and evil.

Flouting the Law

Dr. G. P. WILLIAMS (Carnarvon and Anglesey) said that the ill was very nearly law, and he did not think any section of the community should flout the law, however much they might object to it. There should also be taken into consideration what was at stake for the average general practitioner if he refused to work the Act. To the younger men, with no great margin of solvency, the issue was extremely important. They would lose their panel fees, which were a standby, and would have to exist for an indefinite time on the private fees which they might earn while opposing what had become the law of the land. He was second to none in his objection to many parts of the Bill, but once it was law they could not afford deliberately to oppose it, any more than the master bakers could oppose bread rationing. What mattered to 99% of general practitioners in this country was whether they were going to make a living wage.

Dr. W. S. MACDONALD (Leeds) said that once more he had the temerity to put an opposite view to that of the Chairman of Council. Dr. Dain had said that what they were considering was the progress of medicine and the welfare of the patient. But that was also the professed objective of the Government, so why was it impossible to play together in the same team? The profession had a real responsibility to the public, and he suggested that the main difficulties of the Negotiating Committee in meeting the Minister were not due to the fact that the Minister was himself somewhat difficult to negotiate with. The Minister represented the Government, and the Government was supported by a Parliament recently elected by the public, of which the profession was only a section. If they were going to over-emphasize the difficulties which they as a profession had with the Government, inevitably they would come into greater difficulty, and the result would not be to the credit of the profession.

Mr. C. E. BEARE (Reigate) said that it was not a question of flouting the law. They were given the option of coming into the Service or standing out, and if they did the latter they were not flouting the law.

Dr. J. A. BROWN (Birmingham) said that some misconstruction might be put upon one thing that Dr. Dain had said. He had said that those who were Socialists and voted for the present Government would agree to work the Act, while those not Socialists would not. He was sure Dr. Dain had no intention of making this a political issue. Their action had nothing to do with their politics; the only consideration was the health of the nation and the freedom of the profession.

Dr. H. S. PASMORE (Kensington) said that the recent Special Representative Meeting arrived at clear-cut decisions, and he did not know why they were discussing this matter at all. None of their principles had been accepted by Parliament. The fight, therefore, was on. The medical profession was one of the bodies of relatively free men left in this country. Let them keep the right to carry the torch of freedom through these difficult years.

At this point Dr. J. A. BROWN again proposed, and Dr. COCKSHUT seconded, that the meeting go *in camera*, but Dr. DAIN urged that the discussion continue in public. This was a national matter of great importance and they had nothing to hide. Dr. E. A. GREGG thought it would be most unwise, having gone so far, to declare that now they wanted to talk privately. It would give the impression that they were afraid of something, and they were afraid of nothing. If there were some in the hall who wanted to say something contrary to what had been said it would be cowardly if they did not say it. Dr. S. WAND supported the proposal to go into committee to discuss some domestic matters arising out of the resolution before the meeting.

The meeting again decided that the discussion should continue in public.

Dr. R. G. GORDON (Bath) said that there were two points which he would like Dr. Dain to make perfectly clear. His own Division was of opinion that a referendum should be taken soon. The principles already established must be taken together, especially three of them relating to general practitioners—namely, those referring to the buying and selling of practices, to direction, and to salary. These hung together.

It must be made perfectly clear that in objecting to Government action in these respects they were not letting down their patients, that they were still going to serve their patients, and that the patients themselves would suffer if their principles were weakened. In relation to consultants and specialists Mr. Bevan had tried to split the profession, and many consultants and specialists found the hospital service terms somewhat attractive. The question of ownership of hospitals was regarded by many people as not entirely a medical matter. Were they going to include in those principles which hung together this further question of the ownership of hospitals, which was bound up with the question of entrance into the Service of consultants and specialists?

Mr. R. SCOTT STEVENSON (Gibraltar) said that the question to be put to the profession was a simple one, needing a clear-cut answer. It was not a case for another elaborate questionnaire. He begged the meeting to abide by the results of a referendum, which should be taken as soon as possible.

Dr. H. H. GOODMAN (Newcastle-upon-Tyne) said that Dr. Dain had mentioned four points; he would have liked him to add two more: that both doctors and patients who remained outside the public service should not be penalized, and that there should be no penal clauses of a criminal kind in the Bill. He thought that the lead should be given now and not later. The Bill would be implemented very insidiously, and a good many doctors would be caught up quickly in the maelstrom. The Council had its full instructions at the recent S.R.M. Dr. F. ROBINSON (Swindon) said that the talk about flouting the law was a red herring drawn across the track.

Negotiations: A Query

Dr. E. A. GREGG said that the question had been agitating the minds of some of them as to whether the right time to make their decision was now or later on, when the whole picture could be seen and regulations were made under the new Act. He could not help feeling that the more they looked into the possibility of entering into negotiations regarding regulations the more completely would they realize that to do so would mean that they were beginning to work the Act. (Hear, hear.) They did enter into negotiations with the Ministry on what should be considered the capital value of their practices, and he had heard remarks that the doctors were treated generously. No such term was used at the time; an attempt was made to estimate what was the value of their practices, and perhaps they had been unwise to allow themselves to be led even into that. This was the moment of decision, but they must bear in mind that if they made the decision in one way it was going to mean something comparable to what Mr. Churchill promised when he took office early in the war—blood and tears and toil and sweat. In a word it would mean sacrifice, and it was for each of them to see that he shared in bearing the sacrifice of all.

The CHAIRMAN OF COUNCIL said that he had come to the conclusion that they had been wrong in entering into negotiations on the sum to be taken as compensation for loss of goodwill in practices. They had said quite plainly that they did not approve the principle of surrender of goodwill, but they could not get away from the implications of such negotiation, and when they were asked in the same way, without prejudice, to discuss the question of remuneration, he declared at once that it could not be done without involving them in undesirable implications. To discuss regulations "without prejudice" would be a fatal mistake. He was satisfied that if they allowed themselves to go into such negotiations on detail they would be giving way on their principles.

A good deal had been said about opposing the law. They were a profession of free individuals at the moment. They saw no reason why a State health service should not be still free for them to enter or not according to their own particular method of earning their living or their train of thought. He saw no sense in making the point that they might be opposing the law.

As to the suggestion that they should try to agree with the Minister, the Minister refused to play. The Minister said that there was "nothing doing" on principles. This Bill was a skeleton, to be carefully covered by regulations, so that its deformities were not at first revealed. To vary the figure,

it was a fence within which they would be invited to work, but from which it would be difficult to escape—very nice to work in, until one wanted to get out. The Minister had said that he proposed to set up regional boards forthwith. In his view the profession should take no part in the setting up of regional bodies until the Minister had conceded their principles.

Referendum or Plebiscite

Dr. E. W. GOODWIN (Leicestershire and Rutland) moved to recommend to the Council the desirability of circulating a referendum to each consultant and general practitioner when the time is deemed opportune.

"The referendum should seek to ascertain whether the individual is willing to accept or not to accept service under the terms of the new health service. In addition it should point out that should the individual's reply be to decline service then such refusal should not be effective unless at least 75% of the replies are against accepting service. This figure of 75% should apply to the area of each individual Branch and also to the total number of Divisions or Branches in the Association."

Dr. Goodwin said that if members were willing to sell their practices to the Government on the Government's terms and conditions, to work in a Health Centre owned, staffed and equipped by the local authority, to be paid partly by basic salary and partly by capitation fee, to go cap in hand to a committee for permission to leave one place of practice for another—in a word, if they were willing to become an impersonal cog in a bureaucratic machine—they would have no hesitation in accepting service under the new Act. But if they detested all these things, but were forced by stern necessity to make an adequate living, what were they to do and what was the alternative? The first essential was the unity of the profession. It was with a view to ascertaining the true feeling of practitioners that the second part of the motion was inserted, so that the fear of consequences and possibility of duress could not operate.

Dr. A. BROWN (Cambridge and Huntingdon) moved as an amendment:

That a referendum of the whole profession should be taken now on the simple issue whether negotiations with the Minister on regulations should take place or not.

He did not think they had any right to say what was the opinion of the majority of the members on this matter. He agreed that they should have at least 75% of the members unanimously in favour of refusing service before they asked anybody to refuse service. Dr. C. M. STEVENSON (Cambridge) thought that there must be two referendums—the first on the question whether or not to negotiate, and the second, to be taken next summer or autumn, on the question of acceptance or refusal of service. Dr. R. O. EADES (East Suffolk) said that there was hurry in this matter. The Minister was not slow. In his own area the Minister had already got a skeleton advisory board. Dr. A. G. HOLMAN (East Norfolk) supported the amendment. The time was ripe for a referendum to the profession.

The CHAIRMAN pointed out that at the recent Special Representative Meeting a resolution was carried that there should be a referendum. The only question now was as to its date and character.

Dr. LAURIE SMITH (Blackpool) could not agree that the referendum should be in two parts. His constituents felt that to send out a referendum to all practitioners in the country before they had received from the other side of the table any idea of how they were going to be remunerated was folly.

Dr. TALBOT ROGERS (Bromley) supported the idea of a plebiscite, but said that it should be taken after due consideration of what it was they wanted to ask their colleagues and after making quite certain that they realized the full implications of their answer. A number of them said they had not got the full picture. Admittedly there were some good things in the Bill, and a few good things had been added in the committee stage, thanks to their conversations with the Minister. It was quite possible that during the regulations stage they might get the Minister to listen to their experience, so that they might play quite a big part in the framing of workable regulations which would not penalize the profession. When the whole picture of the regulations was worked out the feeling of the profession could be tested. This matter

should not be entered upon hastily. A Special Representative Meeting should be called to decide whether to have a plebiscite and what should be its terms.

Two Referendums?

Dr. ROSS (East Hertfordshire) agreed with a previous speaker that there must be two referendums. Practitioners had a year and a half in front of them before they decided what individually they should do. Dr. H. B. MUIR (Fife) said that among certain of the senior members in his Division he found a "Spens Committee narcosis" and "compensation jitters." Some of them said that while they stood by the principles they were afraid that for financial reasons they would be forced to accept service. Dr. HELME (Guildford) also felt that in all probability there should be two referendums—one taken immediately on the principle whether discussion regarding the formulation of regulations should take place and another later on to find out exactly what action might be determined on a measure which would then be law.

Mr. LAWRENCE ABEL (Marylebone) said that the Minister had at an early stage declared that there would be no negotiations. Dr. Dain had given them a fighting speech; he had reminded them of the main principles which were laid down on the last occasion. What, then, did they care for regulations? They would be only further fetters to bind them. To discuss now by referendum or plebiscite whether they should or should not enter into conversations with the Minister on something they were not going to accept at all was ridiculous. They had to distinguish between two lines of action—going further with a Minister who would not negotiate, and, alternatively turning the whole thing down. These regulations would be started in the autumn, and there would not be time to act on a plebiscite then.

Dr. F. GRAY (Wandsworth) supported the Cambridge and Huntingdon amendment except for the word "now" ("referendum . . . should be taken now"). The proper time to take this referendum was as soon as possible after the Bill became an Act, and this for two reasons. The Bill had still to go through the House of Lords, and while he would not raise any false hopes as to what might happen there, it would be impolitic to assume in advance that there would be no further amendments. They wanted this referendum to go on to a profession which would fully understand the issues and implications involved, and if they waited a short time—until approximately, the beginning of November—they would have an opportunity of bringing home to every member of the profession the importance of the issues and the seriousness of the decision which he was asked to take. The question to which they must have an answer was "Do you, or do you not, accept the main structure of this Bill?" Mr. C. E. BEARE (Reigate) considered that it was most important to take a plebiscite now to get full support for their principles. Dr. J. A. IRELAND (Shrewsbury) said that if they went on to discuss the question of regulations they would have accepted the Bill as it stood and would be committed indefinitely.

Timing of the Referendum

The CHAIRMAN OF COUNCIL said the problem was that of timing and the nature of the question to be asked. He suggested that it would be wiser to leave the timing to the Council to decide. They must discover from the members of the profession whether a sufficient number of them would be prepared to refuse service on the principles, or not to take service until the principles had been conceded by the Government. The question must be asked in such a form that a practitioner could say whether, because of the principles which had been adopted, there should be no negotiations on regulations, but those who said that must be prepared to act on it and to undertake that whatever regulations emerged they would still not be able to accept service because of the form of the Bill. It was essential to know before very long how their members stood with regard to the first question of adherence to the principles. As to the time, he thought the Council should be left to choose it—in the course of another six or eight weeks.

Dr. A. BROWN, the mover of the Cambridge amendment, said he was prepared to leave it to the Council as to when the referendum was taken, but it must be soon.

The CHAIRMAN OF COUNCIL: How are we to interpret the word "now" in the Cambridge amendment?

Dr. BROWN (the mover): "Soon."

The amendment:

That a referendum of the whole profession shall be taken soon on the simple issue whether negotiations on regulations with the Minister should take place or not

as carried. On its being put as a substantive motion, Mr. LAWRENCE ABEL (Marylebone) moved as a further amendment:

That this meeting recommends to the Council the desirability of the plebiscite including personal contact with each member of the profession as soon as this can be arranged.

He said that at first sight this looked as if Dr. Hill had got to knock on the front door of 50,000 doctors. But this work might be allocated among local "disciples." Mass meetings are less satisfactory; only 50% of the profession turned up, and that was the half already interested. Ten or fifteen men in each Division could surely be found who would undertake to contact every practitioner. The question was not one as to whether "twelve-and-six was going up to fifteen hoh," it was a question of sticking to principles. Dr. Dain wanted to know the date when the question should be asked, and the form of the question. Of course there must be no coercion, but each man must be made to feel that he was in the body of the profession and that his decision was important. The date should be fixed before the Minister started to form his regional boards; indeed, he was forming them already, and some of the "quislings" were already in office. The manner of the contact must be personal. A good deal of it could be done "at the back of the hall when Dr. Hill has done his stuff in twenty different districts on twenty consecutive days." (Laughter.) Let them give National Health Insurance the go-by for a year or eighteen months and go back to private practice. It would do the young men a power of good to go back to private practice and not to be able to rely on the Government cheque.

Mr. Abel's amendment was put to the vote and carried, 126 voting in favour and 71 against.

A REPRESENTATIVE: Is it humanly possible to carry out this amendment?

The DEPUTY CHAIRMAN (temporarily presiding): The actual thing that has been passed is the amendment, not the speech in support of it. (Laughter.)

When Mr. Abel's amendment was about to be put as a substantive motion, as a continuation of the Cambridge amendment "That a referendum of the whole profession be taken on the simple issue," etc., however, Mr. ABEL himself objected. He said that he was in a complete muddle over this. He did not know that his amendment was to be dovetailed into the Cambridge proposition. He thought they had better start again. His amendment was not to the Cambridge amendment, but to the original motion by Leicestershire and Rutland. The meeting had supported Dr. Dain in his plea for adherence to the principles, but now it was in danger of discussing regulations, which would imply acceptance of the Bill. He wished to withdraw his amendment.

The DEPUTY CHAIRMAN said that Mr. Abel was in the unique position of opposing an amendment which he had himself proposed and had succeeded in getting carried, but he was not out of order.

Mr. ABEL said that there had been a misunderstanding, and he asked the meeting to reject his amendment as the substantive motion.

The SECRETARY, who was asked to clarify the position, said that the meeting began with the consideration of the Leicestershire and Rutland motion. That motion was amended by Cambridge and Huntingdon, that a referendum of the whole profession should be taken soon on the simple issue whether negotiations on regulations should take place or not. On the substantive motion a second amendment was then moved by Mr. Abel which, on the interpretation of the Chair, amplified but did not remove the Cambridge amendment. Therefore, on the substantive motion the issue before the meeting was whether it approved the Leicestershire and Rutland motion as amplified by Cambridge and as further amplified by Mr. Abel's amendment. If the meeting accepted the view of Mr. Abel that his amendment destroyed the Cambridge amendment, it would reject the substantive motion now before the meeting.

If it desired Mr. Abel's amendment to be an amplification of the motion by Leicestershire and Rutland as amended by Cambridge, then it would vote in favour of the substantive motion.

The substantive motion was put to the meeting in the following form:

That a referendum of the whole profession should be taken soon on the simple issue of whether negotiations on regulations with the Minister should take place or not, and that the meeting recommends to the Council the desirability of the plebiscite including personal contact with each member of the profession as soon as this can be arranged.

This was carried.

Dr. G. F. BURNELL (Cornwall) desired to move a rider that the acceptance of an appointment to a regional board now should be regarded as the act of a "quisling," and the profession should be notified of this decision, but this was met by a motion to proceed to the next business, which was carried.

Suggested Covenant

Dr. F. ROBINSON (Swindon) moved that a suitable covenant should be drawn up by the Association and signed by all medical men as a guarantee of unity. He said that it would be impossible to build up any service unless the traditions of a free profession were behind it. His proposal would make it possible to deal with those people who were not prepared to stand by their principles. After a man had put his name to such a covenant he could be held to it by his Division. The covenant should emphasize loyalty to the Association, and it should be worked by the local secretaries. It would have no time factor, and it would be more binding than a referendum.

The CHAIRMAN OF COUNCIL said that he hoped this would be withdrawn. ("Hear, hear.") They did not want to harness to any kind of promise people who could not make up their minds. They wanted people with conviction. The proposer seemed to assume that an enormous number of people were waverers, ready to promise something and then not standing to it. He hoped that the next stage when the answer to the referendum was available might be left to the Council.

The motion was withdrawn.

Alternative Schemes

Dr. W. GUNN (Greenwich and Deptford) had a motion regretting that no reference was made to an alternative scheme for the treatment of patients in the event of the National Health Service Bill proving unacceptable, and suggesting that a list of practitioners be compiled who would undertake to refuse service provided a sufficient number gave a similar undertaking. This motion was before the recent Special Representative Meeting and referred to Council. He did not know what the Council had done about it. The second part of the motion was inspired by a feeling among some members of the Division that certain members would feel more confidence in standing out if they knew that their fellows were standing with them.

Dr. A. V. RUSSELL (South Staffordshire) asked that the following words might be added to the motion: "and that a brief and concise outline of an alternative service be prepared and issued to the press and public, together with a statement of those points in the National Health Service Bill to which the B.M.A. is unalterably opposed." It was not beyond the wit of man to devise a scheme. They had as a basis their own publications—the General Medical Service for the Nation in 1938 and the interim report of the Medical Planning Commission in 1942.

The CHAIRMAN OF COUNCIL said that the Council had not omitted to consider this matter, but on a certain scheme being put to Panel Committees there was no unanimity. Obviously this must be a short-term policy. Any deadlock would not continue indefinitely. To a great extent the ordinary methods of private practice might bridge the interval.

The motion was lost.

(Dr. MILLER at this point returned to the Chair.)

The Safeguarding of Private Practice

Dr. O. C. CARTER (Bournemouth) moved:

That for the safeguarding of private practice, whether general or special, an essential is the preservation of independent private

nursing institutions apart from the hospitals, and there should be no power vested in the Minister under a National Health Service Act to acquire such institutions without the consent of the owners, nor power to prevent the establishment of such institutions.

He said that this was a simple and straight-cut motion, and although it was the only one appearing on the agenda on the safeguarding of private practice, that in no way detracted from its great importance. On the previous day representatives had shown in a definite way that they considered that the preservation of private practice was of great importance. It was important in the interest of the progress of medicine, of the patients, and of the National Health Service itself. Private practice, like any other form of practice, had to be both domiciliary and institutional, and for a very long time there would not be sufficient pay-wards attached to hospitals to accommodate all those patients who wished to be treated privately. Furthermore, there would always be a certain number of patients who would wish to be treated in homes separate from the big institutions. They all agreed that there were a few bad private nursing homes, and the sooner they were shut the better. Indeed, local authorities had power at the present moment to shut homes that did not come up to the requisite standard. But the great majority were satisfactory and well run. It was those homes which would give specialists the added opportunity of practising privately, and would give general practitioners who were not in touch with hospitals the opportunity of treating their own patients when they were too acutely ill to be attended in their own homes. It was unlikely that the Minister would wish to take over many of these homes. This particular issue was raised on the committee stage, and the Minister said that the powers were necessary but would be exercised very rarely indeed. Here lay, however, a big danger. There were large private nursing homes which had been designed, built, and equipped as first-class private hospitals, where there was every modern facility for up-to-date treatment, and owing to the lack of general hospital accommodation the Minister, in looking round for additional premises, might find these institutions a very tempting bait. They were anxious that the "rare occasions" to which the Minister referred should not be reserved for the acquisition of these special homes.

Mr. DICKSON WRIGHT (Marylebone), in supporting the motion, said that nothing was so good for anybody as competition. The competition of these private institutions would be a valuable corrective to the Minister. It should be remembered that if he took over a nursing home it did not necessarily mean that it would be continued as a nursing home. He might make it a health centre or anything he chose.

The motion was carried.

A number of other motions were on the paper concerning terms and conditions under the new National Health Service. Dr. J. A. MACDONNELL (West Middlesex) moved, and Mr. B. HOLDEN (Macclesfield) seconded:

That in view of the decision of this meeting to await the result of a referendum on the question of whether or not negotiations with the Minister should take place on the questions of regulations, as most of these motions deal with regulations it is a waste of time for this meeting to discuss them.

This was carried, and the agenda under "National Health Service" was thereupon completed.

PUBLIC HEALTH

Dr. J. FENTON, chairman of the Public Health Committee, introduced the section of the Annual Report under "Public Health."

Remuneration for Part-time Employment by Local Authorities

He first moved, as a recommendation of Council, the substitution for the existing scales of new scales for the remuneration by local authorities of medical practitioners employed by them on a part-time basis. The new scales were set out at length in the Annual Report of Council (*Supplement*, April 20, p. 94). Dr. Fenton explained that the existing scale was issued in 1943, and he indicated the increases, in some cases considerable, in others modest, in the scale now proposed to replace it. The new scale had been approved by the Council, but it had not been discussed and negotiated with the associations of local

authorities. The 1943 scale was quite inadequate, and this represented a satisfactory improvement.

Mr. C. E. BEARE (Reigate) said that the fee for consultant and specialist sessions of two hours' duration was five guineas, which it seemed to him was insufficient. During such a session two major operations might be performed. He thought there should be a fee per operation.

A Brighton amendment expressing dissatisfaction with the scale was not carried.

Dr. I. G. INNES (East Yorkshire) had an amendment regretting the continued chaotic state of the scales of remuneration for practitioners on an item-of-service basis. He gave examples of the various anomalies. Dr. FENTON said that this was not a criticism of the new table but of another range of fees. A good deal of unification was, in fact, achieved in the new scale.

The amendment was lost.

An amendment by Hendon called for a fee of 5s. per injection for immunization at a doctor's surgery, and of 7s. 6d. a visit to the child's home for this purpose. The fees proposed in the scale were 3s. 6d. and 6s., respectively, the latter plus mileage. Dr. FENTON said that there was very little difference, and it would be a pity to disturb this carefully worked out scale for so small a thing.

This amendment also was negatived.

Salaries in the Public Health Service

Dr. FENTON, in moving approval of the formula agreed upon concerning salaries in the public health service (set out in paras. 58-62 of the Annual Report), said that this matter arose from an instruction given at last year's A.R.M. The Askwith agreement terminated on March 31, and it would take a considerable time before a further agreement was negotiated. In the meantime the Council had endeavoured to secure an interim percentage increase in remuneration equal to 30 per cent on salaries of under £1,000, and 20 per cent on salaries of over £1,000. At a conference with associations of local authorities they were offered a 30 per cent. increase on salaries of £700 and under, 20 per cent. on salaries of between £700 and £1,000, and 10 per cent. on salaries of over £1,000. They had accepted this because, although it was not what they asked, it did bring relief to the people about whose position they were most concerned. The acceptance of this interim arrangement had been without prejudice.

Dr. H. M. TURNER (Sheffield) moved to express dissatisfaction with the result of the negotiations on the interim revision. The lines on which these negotiations were conducted should not serve as a precedent. There was no reason why the approach should not have been made much earlier. The conference itself was badly arranged, for a small delegation representing the B.M.A. was confronted by almost a mass meeting of associations of local authorities, so that the B.M.A. was placed in the position of a suppliant deputation asking for an improved wage from employers. Again, from a psychological point of view, it was wrong that the delegation should have been led by a full-time officer of a local authority. He was casting no reflections upon Dr. Fenton, whom they all liked and admired, but there was plenty of other talent on the Council, and some man who was not and never had been in an employed position to a local authority should have led the delegation. The proposals originally put forward by the delegation were too complex. They embodied the principle of differentiation of percentage increase according to salary, a principle never accepted by the profession, although established by the Treasury. The delegation should have asked for a flat percentage increase, and any negotiation should have taken place merely on the figure. The outcome of the negotiations was a most complex schedule, operating hardly upon senior clinical officers. The senior clinical officer of specialist status who might have the highest qualifications, and who pre-war was paid £1,250, was not entitled to any increase under this award. Dr. Turner went on to say that the B.M.A. had never taken a proper interest in and care over negotiations of salaries for whole-time clinical officers, such as these officers were entitled to expect from the Association, and it was felt at the present time, when more important negotiations were pending, that it would be well for the Council to overhaul its negotiating machinery both in its actual form and in its less tangible aspects, so that there should be no repetition of this type of negotiation.

f negotiations in future were conducted in the same spineless manner the outlook was a little bit bleak.

Dr. J. HALLAM (North Staffordshire) agreed with the Sheffield criticisms. It appeared that the only people to benefit from these interim scales were those who were not able to meet their financial commitments. His Division, of course, had every sympathy with these men, but it seemed a little bit hard that no arrangement had been made in connexion with the others. He was informed that at a meeting of county medical officers of health it was ascertained that, out of 22 present, only 2 benefited in any way from these interim awards.

Dr. SMITH (Lanark) hoped that steps would be taken to make similar scales applicable to Scotland. Dr. H. B. MUIR (Fife) said that no doubt the committee had made the best of a bad job, but it was a pity, especially at the present time, that the committee accepted interim proposals which would prejudice the negotiations for a final agreement. Dr. COOKE (Derby) also expressed dissatisfaction with the scale. He hoped that pressure would be applied to obtain an early agreement on new "Askwith" scales. It had been stated that this interim agreement would continue for two years, which was a long time for an inadequate award. Could not the introduction of the new scale be accelerated?

Dr. FENTON replied that, with the settlement of these proposals, steps would be taken to secure their application to Scotland. The Sheffield representative had made his criticisms in a pleasant way, but they were not all justifiable criticisms. He had objected to the methods of approach. Last March they approached the Minister of Health with regard to the interim awards, and he called a local authorities' conference. It was difficult to see what objection there could be to that. It was said that the Association's delegation was a small one of six or seven, whilst there were 40 or 50 on the other side. That was true, but it was an advantage to have representatives of all local authority associations present. Every association of local authorities had accepted the agreement. Another objection was that it was unfortunate that the delegation should have been led by a whole-time medical officer of health (himself); but as a matter of fact the delegation was led by Dr. Dain, and in the public health service they were very grateful that he should have come and lent it prestige. It was also said that the negotiation was "spineless." Dr. Hill was there and took part in it, and none of them thought it spineless. If they were not satisfied with the result, they got the best they could.

The Sheffield amendment was lost, and the appropriate section of the Annual Report was approved.

National Maternity Service

Dr. FENTON next moved approval of the part of the report which recounted the meetings with the Royal College of Obstetricians and Gynaecologists concerning the conflict between that body and the Association over the practice of midwifery by the general practitioner. It had been the policy of the committee to secure that there should be no new criterion whereby general practitioners might be prevented from entering the midwifery service.

Dr. R. FORBES (Hendon) moved:

That the Council be instructed to oppose the introduction of new criteria of qualification sponsored by the Royal College of Obstetricians and Gynaecologists or the Ministry of Health, which would have the effect of precluding any competent general practitioner from engaging in the practice of midwifery among public or private patients, if and when he so desires.

It was felt by Hendon that the Council had failed to give further support to the proposition that was accepted by the Representative Body last year, and it was desirable that they should say it again, and in definite terms. They were conscious that if the criteria such as were foreshadowed by the Royal College were adopted and applied, even if only to a section of the profession engaged in the public service, it would not be long before they were made of more general application. It was essential to retain all that had been gained by simple admission to the *Medical Register*, and the introduction of new criteria must be resisted.

Dr. G. PRIESTMAN (Bradford) moved to reaffirm the resolution of the A.R.M., 1945, pledging the Representative Body to resist the introduction of any new criteria of qualification in

midwifery that would, if officially recognized, deprive any registered medical practitioner of the right to practise midwifery in a national service, and to add the following rider:

That this meeting considers it irrational that a student should be instructed and qualified to practise in midwifery, and subsequently be refused permission to practise that subject without further instruction following qualification.

The recommendations of the Royal College cut into the whole idea of the relationship of the family doctor to his patient. In the proposed general practitioner hospitals there should be a number of beds set aside for maternity purposes. They would be under the direction of an obstetric specialist, but the visiting general practitioner could conduct the cases.

Dr. Priestman agreed to withdraw his amendment in favour of that of Hendon, and the amendment moved by Dr. Forbes was carried unanimously. A further amendment by Greenwich and Deptford was carried, expressing the opinion that for the purpose of the future health service any general practitioner who desired to undertake obstetrics should undertake to remain efficient in midwifery.

Fees for Antenatal Examinations

Dr. W. LIVINGSTONE (North Staffordshire) moved: "That in the opinion of this meeting the fee payable by a local authority for a full antenatal examination and report should be two guineas." This might seem a big increase on 12s. 6d., but there was the question of consistency. In an earlier recommendation the Council had taken the view that two guineas was a reasonable fee to charge an insurance company for a complete examination and report, and yet they were prepared to accept 12s. 6d. from a local authority for a similar examination and report, plus vaginal examination and pelvic measurement. The responsibility entailed was greater than that which the doctor accepted when he examined a person for insurance. If the antenatal examination was not done properly then the health or life of the mother or child might be put in jeopardy. If the profession was prepared to work at uneconomic fees the Minister of Health, in making the regulations for any future service, would take them at their own valuation.

Dr. FENTON pointed out that the meeting had already adopted a scale of salaries which conflicted with what was being urged by North Staffordshire. The real danger of asking for a fee of two guineas for one antenatal examination was that local authorities would ask doctors to give them a session of two hours for three guineas.

The motion was lost.

Fees for Attendance at Confinements

Dr. LIVINGSTONE further moved that the minimum fee for attending a full confinement under local authority arrangements should be five guineas. In North Staffordshire the local authority paid a general practitioner three guineas for a confinement. If eight visits were paid after the baby was born, and assessing each visit modestly at 5s., one was left with the handsome sum of 23s. for attendance from the time the practitioner was first called until after the baby had been born, the placenta delivered, and one was perfectly certain that all immediate danger was past. This might entail three or four visits to the patient's house; it might mean two or three hours spent there, possibly during the night. What other members of a profession would get up in the middle of the night and do two or three hours' work and accept 23s. for it? Would a lawyer do it when hurriedly summoned to take depositions? Each of these confinements was, presumably, an abnormal case. The midwife was not permitted to call in a doctor unless she felt that some abnormality was present, and this meant that the doctor was acting as a specialist, and for this he received 23s.

Dr. FENTON suggested that as the motion, if it was made effective, would require an alteration of the regulations, it should be sent to the Council for necessary action. The motion was carried.

The Safety of Milk

Dr. HOWIE WOOD (Isle of Wight) moved:

That this meeting is of opinion that legislation should require that all milk sold to the public should be either pasteurized or from tubercle-free herds.

Last year the meeting passed a resolution that all milk sold to school-children should be safe milk. The resolution was borne aloft on the powerful pinions of Mr. Lawrence Abel and disappeared into the blue, and what eventually came down was something rather different. The Representative Body found itself in the position of having nailed its flag to the mast of pasteurization. Good as pasteurization was, it was even better to give school-children in particular and the public in general milk from tubercle-free herds. His own Division was an agricultural community, and on the island the agriculturists had made successful efforts in the breeding of such herds. They thought it in the national interest that such breeding should be encouraged, and they were anxious lest any decision by that meeting should mean the encouragement of the production of dirty milk rather than that herds should be bred tubercle-free. School-children in his area were receiving milk which, on the admission of the public health committee, contained living tubercle bacilli. This was absolutely wrong, and a thing which should be stopped without delay. The Ministry of Health had given the opinion that milk should be either heat-treated or tuberculin-tested. The purpose of this motion was to ensure that milk be either pasteurized or from tubercle-free herds.

Mr. LAWRENCE ABEL (Marylebone) moved to insert after pasteurized "the words "or boiled," and at the end of the motion to add the words "and that this should be emphasized immediately to the Minister as a matter of urgent national importance." Appeals like this had been made for many years. He had seen several of his friends in the profession lose their children from tuberculous meningitis—doctors who had not taken the trouble to see that the milk was boiled. Figures were given showing the incidence of bone and joint tuberculosis. To whom could they appeal? Appeals, largely unavailing, had been made to the Minister and to parents. It had occurred to him that an appeal might be made to the children themselves, and he had jotted down a variant on nursery rhymes:

Little Miss Muffett, sat on a tuffet,
Eating her curds and whey,
But the milk was not pure, and was too like a sewer,
And carried Miss Muffett away.

Hey diddle-diddle! The cat and the fiddle,
The cow was full of T.B.,
The milk which was given took our children to heaven,
Although we appealed to A.B.

And, finally, the following:

Listen, Mr. Bevan,
T.B. leads to heaven,
Kids are getting fewer,
Give us milk that's pure.

(Laughter and applause.)

Dr. COVE-SMITH seconded the Marylebone amendment.

Dr. SMITH (Lanark) said that he had spent some 25 years in the treatment of non-pulmonary tuberculosis. In the pre-war years, of all the cases he treated which were typed, roughly 20% were bovine; during the war years this figure rose to 31.8% per cent, and this was due to milk. The cities of Glasgow and Edinburgh some years ago, after the medical officers of health had paid a visit to the United States, endeavoured to put through a Bill to make all milk entering those cities pasteurized, as in New York, Montreal, and Quebec. He added that in his area they had as many tubercle-free herds as in any other, but even so he would not allow unpasteurized milk to be given to children. There was no argument against pasteurization. Any vitamins lost in the process could easily be replaced. It was startling that owing to the fact that much milk in this country was unsafe the soldiers of our Allies during the war could not be fed with British milk.

Dr. O. C. CARTER (Bournemouth) did not feel that the rearing of tubercle-free herds was an alternative to pasteurization. Milk carried other diseases besides tuberculosis. Abortus fever in his part of the world was not uncommon. He reminded the meeting of the typhoid fever epidemic in Bournemouth some years ago, which was due to contaminated milk, and as a result of which 120 people lost their lives.

Dr. J. M. GIBSON (Huddersfield) said that as a medical officer of health he was very keen that they should have milk free

from tubercle for supply not only to children but to adults. In his experience even milk from a tubercle-free herd could not be guaranteed to be free from tubercle. The cows in such herds, as in other herds, were constantly changing, and it did happen now and then that milk from tubercle-free herds contained tubercle bacilli. With regard to the suggestion to include boiled milk as an alternative, he hoped the meeting would disapprove and would insist on pasteurization, which ensured the only safe and reliable milk.

Dr. J. B. W. ROWE (Harrow) referred to erroneous public statements to the effect that there was no need to pasteurize milk, and appealed to the Press to publicize the insistence of the Representative Body on the vital importance of a safe milk.

Dr. HOWIE WOOD said that from the point of view of palatability a glass of fresh milk was, of course, much to be preferred to a glass of heat-treated milk, so that it was much easier to get children to take the former, and incidentally the vitamin-content was not impaired in any way. A lot of drivel was talked about raw milk. If the milk was collected in a proper milking machine and fed direct into bottles, after cooking, being absolutely untouched by hand, it was as safe as and far more palatable than any of the heat-treated milk.

The amendment moved by Mr. Lawrence Abel to the Isle of Wight motion was put and carried.

Dr. J. M. GIBSON then moved a further amendment to leave out the words "or boiled." It would be a great mistake to countenance the sale of boiled milk to the public. Boiling changed the whole character of milk and spoiled it entirely and it opened the door to careless people to heat the milk again and again to prevent it from going sour.

Dr. A. SMITH said that it would not be advantageous to have milk boiled if one were certain of efficient pasteurization, but in many areas efficient pasteurization was not carried out, and until there were sufficient large pasteurization plants some such expedient must remain.

Mr. ABEL said that he was told it would take several years before pasteurization plant would be available; nor was transport available to take the milk in bulk and get it pasteurized. To get tubercle-free herds would be a matter of twenty years. Dr. GIBSON could not agree that to secure general pasteurization of milk would take an undue time.

The amendment to leave out the words "or boiled" was carried.

After some further discussion on a form of words which would represent the feeling of the meeting the CHAIRMAN of COUNCIL suggested the following:

"Ideally all milk should be obtained from disease-free herds under the best hygienic conditions. In the meantime all milk should be pasteurized, or, where efficient pasteurization is not available, boiled; and this should be emphasized immediately to the Minister as a matter of urgent national importance."

This was seconded by Mr. ABEL and put to the meeting and carried unanimously.

PUBLIC RELATIONS

The CHAIRMAN of COUNCIL, in introducing the report under "Public Relations," said that the relationship of the Association and the Press had greatly improved, and the Association views were now set out much more fully and regularly than they used to be. He congratulated the Public Relations Officers in the Divisions on what they had done in making their position in regard to the National Health Service proposals better understood by their respective publics.

Dr. ALICE GILBY (Westminster and Holborn) had an amendment declaring that relations with the Press were still not entirely satisfactory. The Press had appeared to concentrate on two of the main aspects of the Bill—namely, hospital problems and specialist problems—but had largely ignored the unfavourable provisions concerning general practice.

Dr. DAIN said that he fully agreed that, while in general their relations with the Press were good, they might be better, and he was willing to accept the motion as an indication that the Public Relations Committee still had work to do.

This part of the report was approved, and the meeting adjourned at 6.30 p.m.

THIRD DAY

Thursday, July 25

The meeting was resumed at 10 a.m.

MISCELLANEOUS MOTIONS BY DIVISIONS AND BRANCHES

In conformity with a previous resolution, miscellaneous motions by Divisions and Branches not appertaining to the Annual Report were taken as first business.

Study Groups

Dr. Ross (East Herts) moved:

That this meeting instructs the Council to advise every Division to establish, where not already in existence, one or more local study groups, in order to secure the wider discussion of medico-political problems, to ensure a more intimate sharing of views, and to attract the active co-operation of more medical men and women in the formation of policy.

He said that now that it had been decided to take a referendum of the profession it was most important that the profession should be as fully informed as possible on the present position, and study groups would be most valuable. Participation in study groups would also foster greater interest in the work of the Divisions, and there would be more informed discussion at Divisional meetings.

The motion was carried.

Compensation for Doctors who are War Casualties

Dr. A. C. E. BREACH (Bromley) moved:

That in the event of the goodwill of practices being acquired by the State and of compensation being paid, the practices of those doctors who were killed or disabled by enemy action during the war should rank for compensation on the basis of the 1939 income in those cases where the goodwill has not already been sold.

He said that their concern was the problem of the doctor who had been killed or disabled as a result of enemy action and the compensation of his heirs for the loss of the value of his practice. This was a case which threw a strong obligation on the rest of them. It was not a matter of charity in any sense at all. What had happened to these practices was that they had been dissolved among the other practitioners in the neighbourhood, who had thus acquired, more or less involuntarily, an asset, and it was up to them to pay for that asset as an ordinary transaction. A fairly typical case was a doctor aged 45 who entered the Services at the outset of the war and whose practice was more or less protected by his colleagues while he was away. After two or three years he was killed, and as that happened in 1942 it was quite impossible to sell the practice at that time; and in spite of the efforts of his neighbours the practice became disintegrated. Therefore at the end of the war there was nothing left to sell, and his heirs were deprived of an asset to which they had a right to look forward.

There were three possible methods of meeting the situation. One was by a levy amongst the profession, but this would have to be voluntary and would be subject to the objections which applied to all voluntary levies. The second was some sort of local arrangement, but it was extremely difficult to assess how much of that practice had been distributed among the neighbouring doctors and how much had disintegrated into a wider field. The third possibility was that when the National Health Service scheme came into being, with its compensation clauses, those clauses would offer a simple way of dealing with the problem of the doctor who did not return. A fair way of treating the situation would be for the practice of the late doctor to be assessed for compensation exactly as if that doctor were living—that is to say, on the basis of the 1939 figures—and the compensation should be payable to his heirs.

The motion was carried.

Postgraduate Study for General Practitioners

Dr. G. DE SWIET (Paddington) moved:

That this meeting wishes to emphasize the crying need of general practitioners for postgraduate study to keep abreast of the rapid advances in diagnosis and treatment; all the more so as the opportunities were few and far between during the war.

He said it was true that the new Bill made provision for postgraduate study, but it was not known how long this would take to organize, and something ought to be done now. It was realized, however, that owing to the scarcity of accommodation for medical students there would be very little room for those taking postgraduate courses. In London the Public Medical Service, jointly with the London Panel Committee, had arranged some very useful courses notwithstanding wartime difficulties, but it was felt that this was only a drop in the ocean and that something on a national scale would have to be done. They looked to the B.M.A. for help in this matter.

Dr. DOUGLAS BOYD (Belfast) moved as an addendum to the Paddington resolution:

That refresher courses should be made available for general practitioners at recognized teaching hospitals, and that they should be facilitated and encouraged to attend them.

He said that general practitioners had found great difficulties in their way in keeping in touch with the work of the teaching hospitals and with the recent advances in medicine. The teaching hospitals should do everything in their power to facilitate refresher courses. In Northern Ireland a great deal had been done to encourage practitioners to attend such courses, and it was very pleasant for the consultant to meet the general practitioner within the teaching hospital and show him some of the work.

The Paddington motion with the Belfast addendum was carried.

Alien Practitioners

Dr. W. E. DORNAN (Sheffield) moved:

That alien medical practitioners who have served as such in the British or Allied Forces and who are now unable to return to their native country should be allowed to practise in the United Kingdom provided they conform with such regulations as may be required under the Medical Registration Acts.

He said that it was his unfortunate duty to propose this motion. He did not know what it meant, and he was quite sure that his Division did not mean what the motion said. He would like it referred to Council.

Dr. DE SWIET (Paddington) supported the motion. "It was a very serious business for the people concerned. But if the motion was carried as it stood it would not really alter the present position. At the present moment any alien practitioner who conformed with the regulations could practise in this country. If it was really desired to do something to help these unfortunate people something new must be done, and the motion should stop with the words "United Kingdom."

Dr. A. BROWN (Cambridge and Huntingdon) desired to delete the words "as such," because there were a number of alien practitioners who had not served as medical officers in the British and Allied Forces but had served in other capacities.

The CHAIRMAN OF COUNCIL hoped that the meeting would not pass this motion in the form of a definite instruction but would refer it to Council. This was a very large problem with a great number of facets. Aliens who were allowed to serve in the Forces were not on the *Register*. He asked that this should be referred to Council for consideration and necessary action.

It was agreed that this should be done.

Suggested Special Bread Rations for Doctors

Dr. HOWIE WOOD (Isle of Wight) moved:

That doctors and nurses, owing to their long irregular hours and seven-day week, should be placed in a category which receives higher bread rations than sedentary workers.

He said that most of those present at that meeting would have a natural diffidence in proposing that doctors should receive larger rations than other members of the community. He was rather surprised to learn, however, at his Divisional meeting that the proposal set out in this motion originated with the wife of one of their members, and in the course of the discussion it transpired that several wives of doctors had suggested to their husbands that they would have the utmost difficulty in making the proposed bread ration serve. Many doctors in rural areas were accustomed to take sandwiches when visiting country surgeries. A doctor who worked for a ten- or eleven-hour day was likely to be more physically fatigued and more in need of extra rations than some labourers

after an eight-hour day. The nurses, too, had a special claim for an increase in their ration. Certain classes of nurses had already been granted an addition, but this did not apply to district nurses, whose conditions of service closely approximated to those of doctors.

Dr. C. M. STEVENSON (Cambridge) hoped the meeting would decisively reject this proposal. The doctor's work was hard, but it was not heavy manual work, and the physiologists told them that mental work did not call for extra calories. Such a motion would alienate public sympathy.

The motion was lost.

The Continuance of Rationing

Dr. J. BOYD (Belfast) moved:

That this meeting protests against any proposal to make rationing a permanent feature of post-war British policy and will protest against any form of discriminative rationing for political party purposes.

He said that there were quite a number of disquieting facts in connexion with the present scheme for bread rationing. About a fortnight ago in a neutral country he had sat down to an excellent meal, with abundance of food, and that particular country at the beginning of the war was in debt to Great Britain; now the shoe was on the other foot. Was there actually to-day a genuine shortage of wheat? In America there was more wheat than in pre-war years. Dr. Boyd added that, quite personally, he felt that the substance of this motion did not really concern the present meeting, but his Division was anxious that it should be moved.

The CHAIRMAN said that Dr. Boyd had condemned himself out of his own mouth. This motion was not the business of the meeting.

The motion was withdrawn.

Medical Education

Dr. I. G. INNES (East Yorkshire) moved:

That this meeting suggests to the appropriate authorities that, in order to expedite the qualification of medical practitioners, the method adopted during the late war of shortening holidays and inserting an extra term in the academic year should be continued.

He said he thought that the wartime procedure of making use of vacations for extra medical education should be continued.

The CHAIRMAN OF COUNCIL said that he hoped the meeting would not lightheartedly enter into the problem of the education of the medical man in this simple and easy way. They would be most unwise to accept the shortening of the curriculum by such a method as this. A Report on the curriculum by an influential Committee of the Association would shortly be forthcoming, and he hoped that the meeting would not express any opinion in advance of the Report.

It was agreed to proceed with the next business.

OVERSEA BRANCHES

The CHAIRMAN, before the section of the Report under "Over-sea Branches" was brought forward, said that public memories were proverbially short, but that meeting at least would remember with gratitude how their members over-seas rallied in 1939 to the support of this country. The medical profession was no less prominent in that connexion—possibly rather more—than other bodies of the community. While they could not say that peace reigned on earth, they could at least say that there was peace over the great waters, and for the first time in seven years their oversea representatives had been able to attend the Representative Meeting with some degree of comfort. He invited them to address the meeting briefly.

Before the oversea representatives spoke Dr. J. L. GILKS, Chairman of the Dominions Committee, referred to some of the work of the year. He said that perhaps the most noteworthy event had been the compensation offered to temporary members of the Government service serving in the Forces who had been interned by the Japanese. Originally very meagre terms were offered to these unfortunate officers, but as a result of representations these had been considerably modified in the officers' favour.

Dr. A. S. MANNADI NAYAR (South Indian and Madras Branch) said that his College in Madras had the privilege of sending

out to military service more than 100 men and women doctors. They gained valuable experience and had been happy in discharge of their duties to King and country. As to what would be the position of the Branches of the B.M.A. in India when the new political changes came about he could not say, but he hoped that there would always be good will and understanding between medical men and women in this country and in India.

Dr. L. A. MOODY brought the greetings of the Jama Branch and pledged its loyalty. They were proud to be connected with this great Association. As President-elect of the Branch he felt that he had gained a great deal from coming that meeting.

Prof. W. A. E. KARUNARATNE said that his Branch in Ceylon considered it a great honour to have one of its representatives at that meeting and offered its greetings and good wishes to the parent body.

Mr. V. G. GRIFFITHS brought greetings from Malta, where they were watching with the greatest interest and sympathy the fight which the Association was putting up. They did so for several reasons, one being that a certain number of Malta doctors would come to practise in this country, and, another because legislation in this country was likely presently to be repeated in a modified form in Malta. They recognized that the British doctors were putting up a fight on principle.

Dr. A. L. LOMAS (New Zealand) said that there was a strong bond of feeling between New Zealand and this country. New Zealand they referred to this country as "home." They had gone through their teething troubles in New Zealand in connexion with the nationalization of medical services—other people might call them "Labour pains." (Laughter.) At a later date it was contemplated that something in the nature of a State salaried medical service would be introduced in New Zealand.

Dr. C. FORTUNE (Western Australia) also conveyed very cordial greetings from his Branch. The Federal Council of Australia had been very wise in sending to this country Dr. Hunter as an observer. As part of the British Empire they looked forward to greater contact with Great Britain in postgraduate education and other matters.

Dr. F. J. BOOTH spoke for Queensland, saying that the doctors there were following with deep interest and sympathy the medico-political crisis through which they were passing in Great Britain. In Queensland they had had a Labour Government for many years, and the profession had experienced difficulties; but on the whole they had weathered the storm.

Dr. C. G. TERRELL (Surma Valley and Chittagong) mentioned that he was last at the Annual Representative Meeting at Belfast in 1937. He gave an account of the position in Assam during the war. The medical profession had to endure a great amount of strain connected with the refugee problem and also with the military projects to meet the threatened invasion, so that the Branch had been unable to function to anything like the same extent as in years gone by. A real attempt was now being made to get things going again. There was an increasing membership of Indian practitioners. He hoped that on a future occasion the oversea functions at Representative Meetings would be revived.

Dr. J. G. HUNTER, finally, conveyed a message of good will and fellowship from the New South Wales Branch and also from the Federal Council of Australia. That meeting afforded the opportunity of making and strengthening personal contact between members over-seas and members and officials at home. He had come over from Australia as an observer to see the reactions of British doctors to the measure which the Government was putting through Parliament, and his colleagues in Australia were delighted to know that this issue was being fought on general principles of professional freedom and not on terms and conditions. That had been their own attitude in their relations with the Government in Australia.

The section of the Report under "Oversea Branches" was approved.

HOSPITALS

"General Practitioner" Hospitals

Mr. R. L. NEWELL, chairman of the Hospitals Committee, introduced the report on General Practitioner Hospitals, which formed Appendix I to the Annual Report of Council (Supplement, April 20, p. 101).

Mr. R. W. GRAHAM-CAMPBELL (Trowbridge) moved:

That this meeting views with concern the implications of para. 5 of the Report¹; and urges the Council to modify the policy herein outlined, and to assist rather than discourage the further development of general practitioner hospitals in small provincial towns.

He said that this paragraph seemed to contemplate an actual down-grading of general practitioner hospitals nearly the level of the old cottage hospitals, places where no major work could be undertaken. The report gave an excellent plan for a utility type of general practitioner hospital, but little was proposed for the preservation and development of small general hospitals, which was what the Council was asked to consider. In the part of the country from which he came there were no big towns, and over an area of 150-180 square miles there were twelve small hospitals, linked by a joint committee of hospital staffs. From the medical point of view these hospitals were regarded not as separate entities but as satellites of the parent hospital in Bath. He believed that these small hospitals did serve a useful purpose in relieving the big centres of a large amount of surgical work, and he asked that the equipment and scope of work of these hospitals should not be diminished.

Dr. J. KERR (Hyde) said that formerly the great hospitals were places where the sick poor received the care and comfort which their more fortunate neighbours were able to command at their own homes; to-day these same hospitals were places where the bulk of the people received the most expert diagnosis and treatment. Specialists and consultants gained much of their skill and wisdom from association with these hospitals. If the family doctor on his part was to retain his skill and wisdom he had equal need of such facilities. In any comprehensive health scheme it would be necessary to establish hospitals well equipped in all towns and villages according to their needs. Every general practitioner should be attached to one of these hospitals. In his own county of Cheshire the small hospitals were exceedingly well conducted.

Dr. N. E. WATERFIELD (Kingston) said that in this report what were envisaged were not the already existing cottage hospitals staffed by all the practitioners in the area, but the setting up of a new type of hospital or the assignment of wards in an existing hospital where practitioners could attend cases which under other social conditions they would attend in the patients' homes.

Mr. A. GREEN (Guildford) said that it would be a loss if the general practitioner hospitals were not considerably expanded so that men going into practice were able to practise as they thought best. The trend of specialism was becoming rather exaggerated. There was a tendency in some hospitals to regard each department as distinctly separate, and the patient as a whole in some instances was inclined to be forgotten.

Dr. HOWIE WOOD (Isle of Wight) said that Dr. Waterfield had not entirely succeeded in allaying the apprehensions of some of them with regard to para. 15, and there was a fear that it might be interpreted outside that meeting, particularly in Government circles, as an excuse for limiting severely the field of the cottage hospital.

Dr. A. MORRISON (Darlington) said that these small general practitioner hospitals were an innovation and were distinct from existing local hospitals. He felt that they were a good thing and should be supported.

Dr. W. S. MACDONALD (Leeds) said that the real difficulty behind the Trowbridge amendment did not concern the general practitioner hospitals so much as the smaller general hospitals, which did not come within this report.

Mr. NEWELL hoped that the meeting would not accept the Trowbridge amendment. Para. 15 had been very carefully worded, and he did not think it discouraged the development of these hospitals; it was aimed merely at discouraging work being done at those hospitals which was better carried out elsewhere.

The Trowbridge amendment was lost.

Mr. NEWELL accepted amendments by Reigate and North Staffordshire, the former declaring that no measure should be taken to limit the freedom of judgment and action of a

practitioner, and the latter that the Association should demand the provision of general practitioner hospitals in any health service scheme.

Dr. G. DE SWIET (Paddington) moved: "That this meeting welcomes the Minister's sympathetic attitude towards closer co-operation between the general practitioners and the hospitals." He quoted some remarks of Mr. Bevan in the Standing Committee in which he had said that he was prepared to make a concession in the case of a general practitioner hospital. Mr. Bevan had said:

"I am prepared to make a concession in the case of general practitioner hospitals. There are instances all over the country where a person who is chronically ill goes into hospital because he or she cannot get treatment at home. It may be that they suffer from something which does not require specialist treatment, but treatment by a general practitioner. I want to make it clear that the general practitioner should give that kind of treatment in a general practitioner hospital. I propose to consider whether it is necessary to put down an amendment to make that clear."

Again, in Clause 48 of the Bill the Minister was prepared to admit the general practitioner to hospital in the capacity of postgraduate student.

Dr. W. GUNN (Greenwich and Deptford) asked the meeting to reject this motion, on the ground that any expression of sympathy with the Minister was likely to be interpreted as weakness.

Mr. NEWELL said that he would prefer the omission of the reference to the Minister's sympathetic attitude; it should merely say that the meeting welcomed closer co-operation between the general practitioner and hospitals.

The Paddington motion was lost.

A motion by Worcester and Bromsgrove commending the Council on its report and trusting that this matter would be kept very much in mind was carried. The mover, Dr. STEEL, said that administrative difficulties ought to be overcome and not allowed to sabotage an excellent scheme.

General Practitioners and Hospital Maternity Cases

Dr. J. C. ARTHUR (Gateshead) moved:

That in any hospital area it is essential that facilities should be afforded general practitioners, either in general practitioner or other hospitals, to attend their own maternity cases, privately or otherwise.

He said that there was no doubt that they would get general practitioner hospitals, though the building problem might delay them. His own experience of building was that five Ministries had to be approached, three different licences obtained, as well as the permission of the local council, and then one had to find, somewhere, a builder. The attitude of the obstetricians in this matter of general practitioners and maternity cases was difficult to understand; it was "trade unionism run mad." The obstetricians appeared to have little confidence in the instruction which they themselves gave to medical students or in the ability of those students to profit by it. The obstetricians must be got to see reason. It was most essential that when these hospitals were established general practitioners should have facilities for carrying out their midwifery in them.

Mr. NEWELL said that they had, of course, suggested that maternity beds should be provided at these general practitioner hospitals, and when they were built such provisions would have to be made. But it need not be laid down as an invariable rule, because there might be adequate maternity accommodation near by.

The Gateshead motion was carried. Two motions by Belfast were also agreed to, one declaring that the confidential nature of clinical records in these hospitals must be maintained, and the other that every hospital must have a committee representative of all the attached practitioners, with adequate representation of the committee on the board of management.

The report on "General Practitioner" hospitals was then approved.

Hospital Administration

Mr. NEWELL next moved the adoption of the Council's statement on hospital administration. This, which appeared in the Supplementary Report, was as follows:

¹Para. 15 states that the general practitioner hospital should not in general include in its work the routine performance of major surgical operations, and that the improvement of ambulance services should increasingly permit of serious operations being carried out in more suitable surroundings.

1. The chief officer of a Regional Hospital-Board should be a medical practitioner with experience of hospital work.

2. The administrative head of a large hospital or group of small hospitals should ordinarily be a medical practitioner, designated medical superintendent.

3. The medical superintendent should have full responsibility for the general administration of the hospital, specialized functions such as accountancy being delegated to the appropriate lay heads of departments. He should exercise his medical functions in consultation with the medical staff committee.

4. The medical superintendent should, where possible, take an active part in the clinical work of the hospital, but should have no clinical control of patients in the medical care of other members of the senior medical staff.

5. In every hospital there should be a medical staff committee, which should be composed of all members of the medical staff in charge of beds or departments and all other senior members of departmental staffs, together with representatives of the junior medical staff and the medical auxiliary staff. The medical staff committee should appoint its own chairman.

6. The functions of the medical staff committee should include consideration of all matters affecting the treatment or comfort of patients.

7. The medical staff committee should nominate representatives to serve as members of the Hospital Management Committee, and all matters submitted to the latter committee on behalf of the medical staff should first be considered and agreed upon by the medical staff committee.

8. There should be established also a nursing staff committee of which the matron should be convenor but not necessarily chairman. The membership of this committee should include ward sisters and representatives of the other nursing staff.

9. The nursing staff committee should be entitled to nominate two representatives to serve as members of the Hospital Management Committee.

In doing so he made a comment on para. 2. The word "ordinarily" had been inserted because there were a large number of lay superintendents who were doing excellent work, and there was no wish to offend that large body. Often the medical staff had more "say" in the policy of a hospital when there was a lay superintendent.

Lay or Medical Superintendents

Mr. DONALD WATSON (Bradford) urged that the phrasing of para. 2 be altered from "The administrative head . . . should ordinarily be a medical practitioner," to "should not necessarily be a medical practitioner." If a medical practitioner desired to become an administrator he should not, of course, be precluded, but in his opinion lay administration was better.

Mr. LAWRENCE ABEL (Marylebone) agreed with the last speaker. There were a number of hospitals, especially municipal, which did not wish to have a medical superintendent. The hospital or group of hospitals should be left the right to make its choice in this respect. The superintendent should be the servant of the medical committee, not in any way director.

The CHAIRMAN OF COUNCIL deprecated any alteration of the words of this paragraph, which had been carefully chosen. If the words were changed they would be made to suggest a preference for a lay administrator. He agreed that many voluntary hospitals were very well managed indeed by lay superintendents, but in fact such lay superintendents were already in a superintending position, their position approximated more closely to that of secretary.

Dr. R. G. COOKE (Derby) hoped that the original statement as put forward by Council would be supported. Lay bodies were making great efforts to obtain as big a place as they could in the administration of the new service and in hospitals. If there was no need for a medical administrator in a hospital why should there be a medical administrator in any branch of the service? Why have a medical administrator in the region if it could all be carried out in lay hands?

Col. A. H. PROCTOR (Naval and Military Committee) said that a medical staff committee might to some extent be an intermediary, but on the whole the authority given to a lay superintendent would make him practically *gauleiter* of the hospital. He thought that a more sympathetic interpretation might be expected from a medical superintendent. A lay superintendent would not have the same outlook, would not be prepared to depart from the strict letter of the regulations when necessary, and, moreover, would not have the same backing of the medical committee.

Mr. NEWELL said that he was anxious that nothing in statement should offend the large body of lay superintendents who had given such valuable service.

Mr. DONALD WATSON said that his argument was based on an experience of voluntary hospitals over many years, which had made him feel that lay administration controlled the medical board was a good thing.

An amendment—"That the administrative head of a large hospital or group of small hospitals should not necessarily be a medical practitioner"—was lost, and the statement of Council was approved.

The Chronic Sick

Dr. F. R. STURRIDGE (Willesden) moved:

That this meeting is of opinion that inadequate provision is present made for the treatment and care of the elderly infirm, and instructs the Council to set up a committee to investigate the whole subject and report.

He said that the first part of this motion would be generally agreed. The Council had suggested that all general hospitals should accept, where practicable, a certain percentage of chronic sick cases. The difficulty was in the words "where practicable" because it was just not practicable under present hospital conditions. His Division felt that the position was so serious the Council should be urged to set up a committee to investigate and report. In one county administrative area of 1 million population there were in public institutions 1,000 in-patients of the elderly and infirm class, and 500 of whom were awaiting admission, and another 400 were in the ordinary hospitals of the district awaiting admission to public institutions. Thus the total number waiting was slightly in excess of the number already in, meaning that the beds for such patients should be doubled. In one hospital 30 to 40% of the admissions were people over 65. The solution might lie in general practitioner hospital and in home helps. One of the pathetic things about the situation was that in some of the hospitals these old people were handed over to newly qualified members of the staff, who were not really capable of looking after the elderly. These patients required a great deal of sympathy and largely of a psychological kind. He thought that home treatment should be developed a great deal more.

Dr. W. D. STEEL (Worcester and Bromsgrove) said that none of these persons were not necessarily ill but were incapable of looking after themselves properly in their own homes. They were looked after by their relatives, but economic circumstances militated against that arrangement. There was nothing for many of them at the present moment but to go to a public assistance institution, still known to them as the workhouse. What was wanted was the provision of homes for these people—residential flats with gardens—entirely at the expense of the State.

The motion was supported by Dr. J. C. YOUNG (Belfast), Dr. H. B. MUIR (Fife), Dr. D. J. MORRISON (Edinburgh) associated his Division with the motion. Nothing was so saddening, he said, as the plight of the aged and infirm. One remedy would be to provide in the new housing a communal kitchen with facilities for sending out meals for these old people, and an arrangement to afford them domestic help. At present elderly people had to go to hospital simply because they were not equal to attending to their own domestic affairs. Dr. ALICE GILBY (Westminster and Holborn), in supporting the motion, suggested that in London assistance should be given to the Invalids Kitchen Society.

Dr. G. MACFARLANE (Lanarkshire) said that in his opinion chronic sick people should be passed through a centre of which those who required general hospital treatment could be sent to hospital. As a member of the Medical Curriculum Committee of the B.M.A. he had urged that medical students should be taught the treatment of the chronic sick, with which so much of their future practice would be concerned. A committee was set up to study this problem it might be a subcommittee of the Hospitals Committee, to which some people specially interested in other than the medical aspect might be co-opted. It was a problem which had its social and economic as well as its medical side. Dr. F. M. R. (Preston) said that with an ageing population the balance was shifting towards the wrong end so that this question of chronic sick was becoming increasingly important. Home surgeons and nurses should be specially instructed in

atment and nursing of these patients. Dr. ELSIE WARREN (Bensington) suggested that means be sought for obtaining priority for these people in the allocation of flats.

The CHAIRMAN OF COUNCIL accepted the suggestion that a committee should be appointed to consider this matter, which was of such great public interest. Anything which the Association could do to bring about better conditions for these old people would be done.

Dr. NOY SCOTT (Plymouth) urged that, to meet the problem of caring for the chronic sick, more active steps should be taken to attract women to nursing and to domestic work. The Luffield Trust reserved its bitterest comments for these cases of the chronic sick. This was not so much a question of ricks and mortar as of personnel. The accommodation was available, but not the nursing staff. Dr. J. A. GORSKY (Westminster and Holborn) also urged that energetic steps be taken to meet the deficiency of nursing and domestic hospital staff as a contribution to the solution of this problem.

All the motions on this subject were accepted.

Rehabilitation

Dr. J. A. L. VAUGHAN JONES, vice-chairman of the Rehabilitation Committee, brought forward the report of Council under his heading. He said that the work was fully recorded in the special *Supplement* of June 29. The factual summary given here might not be quite complete, but it was sufficient to show the extent of the existing facilities. In the final section on "planned rehabilitation" an attempt had been made to show all the factors which went to a complete rehabilitation service, and the necessity for team work in the widest sense of the word. He paid a tribute to Dr. Donald Hunter for his able chairmanship of the committee.

The CHAIRMAN commented upon the importance of this committee, and said that they were indebted to Dr. Vaughan Jones for his succinct presentation of its work.

The report under this heading was approved with applause.

NATIONAL HEALTH INSURANCE

Spens Committee Report

Dr. E. A. GREGG, chairman of the Insurance Acts Committee, moved:

That the Representative Body welcomes and approves the majority report of the Interdepartmental Committee on the Remuneration of General Practitioners.

It was of the greatest importance that the profession should make it clear that it accepted and approved the general findings of the Spens Committee report—a report which would be of the utmost value to the profession. ("Hear, hear.")

Dr. J. A. BROWN (Birmingham), a member of the Spens Committee, drew attention to certain points in the report. One recommendation stated that additional remuneration should be given in areas which proved so unattractive as not to draw an adequate supply of practitioners. He was of opinion that the inadequacy in numbers of practitioners in certain areas was largely due to the miserable capitation fee paid under National Health Insurance. If adequate remuneration were given, with some additional remuneration in certain thickly populated industrial areas, the so-called "unattractive" areas would cease to exist, and there would not be the slightest need for any "direction," either negative or positive. ("Hear, hear.") Then the Spens Committee had the greatest sympathy with the position of the men in the Highlands and Islands. They had been fearfully underpaid, and had done their job with a devotion to duty second to none in any part of the country. The Spens Committee had further said that general practice was the foundation on which all else was built, and had emphasized the need for adequate recruitment in quantity and quality. In that connexion all the members of the Spens Committee were very much aware of the possibility of a falling off in recruitment if the general practitioner was not adequately paid for his services, and if there was not sufficient attraction to men in the profession to go into general practice. He did not want the medical profession to get into the state in which the nursing profession had already got, but unless steps were taken to pay the general practitioner adequately for his services he saw a very real risk to the medical service of this country. ("Hear, hear.")

The motion was carried unanimously.

The Insurance Capitation Fee

Dr. GREGG, on behalf of the Insurance Acts Committee, gave the Representative Meeting an account of the recent approach of the committee to the Minister of Health concerning an increase in the capitation fee. The outcome of three meetings had been that the Minister now proposed to make an increase of 2s. in the fee as from January 1, 1946, the fee thus being increased to 12s. 6d. He repeated the account of the conversations which he had given to the committee three days before, and which was reported in the *Supplement* of July 27 (p. 31), together with the resolutions of the committee, the first of which welcomed the Minister's acceptance of the majority report of the Spens Committee and his recognition of the inadequacy of the capitation fee, but stated that the proposed increase was gravely inadequate, while the second declared that the committee was prepared to recommend acceptance of an interim capitation fee of 15s., to be retrospective to January, but added that if the Minister preferred the committee would be willing that the Spens Committee should be asked to state the implications of its majority report in relation to the current capitation fee, on the understanding that both the Minister and the committee accepted, in advance, the Spens Committee findings.

Dr. Gregg explained to the meeting, as he had already explained at greater length to the committee, that the Minister had wished to associate the application with discussions concerning the remuneration of general practitioners in any proposed future service, but it had been pointed out to the Minister that they represented the Insurance Acts Committee, the executive of the Panel Conference, and that it was not within their province to embark, even if they wished to do so, on discussions of the character he desired. Moreover, certain decisions already taken, such as the determination of the Representative Body not to accept the method of basic salary, precluded such discussions. It was also pointed out that there had so far been no indication from the Minister that he accepted the recommendations of the Spens Committee. Since those conversations a letter had been received from the Ministry (published in full in the *Supplement* of July 27), in which, *inter alia*, it was stated that the Minister fully accepted the substance of the recommendations of the Spens Committee. In support of the committee's view that it was a proper thing for the Spens Committee to consider the implications of its report in relation to the current insurance capitation fee, the Ministry's letter of May 17, 1944, from which the appointment of the Spens Committee originated, had been quoted to the Minister, showing that the committee had good grounds for their suggestion, the Ministry itself having recognized the necessity for an independent inquiry.

The announcement of the figure to which the Minister proposed to increase the capitation fee was greeted by the Representative Body with cries of "Shame!"

The CHAIRMAN said that Dr. Gregg had made a statement of great clarity and comprehensiveness. He suggested that no discussion should take place at that meeting, but that approval should be expressed of the action of the Insurance Acts Committee.

The approval was expressed unanimously.

Regional Medical Service

Dr. J. W. MCCARTHY (Hendon) moved:

That the Representative Body is strongly opposed to the introduction of any machinery whereby the Regional Medical Officer may refer a patient to a specialist for a second opinion without affording the patient's own doctor an opportunity of selecting the consultant and effecting the necessary arrangements.

One had only to read what was said in the Council's report (para. 48) on the exchanges which had taken place with the Ministry on the Ministry's attitude in cases where an insured person was referred to a divisional medical officer for an independent medical examination, and a tuberculous condition was diagnosed, to get some idea of the working of the minds of the Ministry, and what might be expected if the profession came completely under its control. It was surely only courtesy to allow the patient's doctor to select the consultant and make the arrangements. To most people that would seem reasonable, and to those working the service essential.

Dr. W. GUNN (Greenwich and Deptford) supported Hendon. He felt that anything which was likely to encroach upon the individual freedom of the doctor or to interfere with the relationship between doctor and patient ought to be resisted strongly.

Dr. A. W. GARDNER (Brighton) said that it was not only a question of courtesy but of medical ethics. Dr. W. JOPE (Lanarkshire) said that once more he was compelled to ask that Scotland, where they had a different relation to their regional medical officers, should be excepted from this amendment. Dr. N. E. WATERFIELD agreed that this was a matter of ethics. It was the privilege of the practitioner in charge of the case to choose the consultant to whom the patient was to be sent, and he hoped they would insist on that rule being observed even by regional medical officers.

Dr. GREGG said that he welcomed these expressions. This was a matter not only of courtesy and medical ethics but of ordinary wisdom. The course which the Ministry was taking in this respect was likely to discourage the good practitioner and to confirm the indifferent.

The amendment was carried.

Science Activities

Mr. ZACHARY COPE, chairman of the Science Committee, presented the report under "Science." He referred to the good work done by the library, which it was intended to develop. The Association had taken part in the Central Medical Library Bureau of the Royal Society of Medicine, designed to assist in the rehabilitation of the Continental medical libraries. The other scientific activities, relating to prizes, scholarships, lectures, and films, were sufficiently set out in the report.

The report was approved.

MEDICAL SERVICES UNDER THE EDUCATION ACT

Mr. R. L. NEWELL presented the part of the report concerning the development of medical services for the purpose of the Education Act, 1944.

Mr. C. G. SCHURR (Brighton) moved as an amendment:

That this Representative Meeting is dissatisfied with the payments for in-patient treatment of children under the Education Act, and presses the Council to draw up an equitable scale of remuneration.

His Division was far from satisfied with the result of the negotiations on in-patient treatment as set out in Circular 102. A careful and often tedious investigation had to be carried out by the physician or an operation by the surgeon. Surely these services alone were worth more than the 21s. per child which the Minister was prepared to recognize as payment to the hospital for distribution among the visiting medical staff. Negotiations were going on between the local education authorities and the hospitals with a view to the hospitals taking over the treatment of school-children under the terms of the Circular, with the termination of existing arrangements. Up and down the country thousands of general practitioners were watching these preliminary skirmishes, being aware of their repercussions on future events.

Mr. C. E. BEARE (Reigate), in supporting the amendment, said that as regards sessional fees for consulting physicians or surgeons undertaking out-patient treatment, the Ministry had laid down a fee not exceeding three guineas for a session of two hours. But already that meeting had decided that the sessional fees for consultants and specialists employed part-time by local authorities should be at the rate of five guineas.

Mr. NEWELL said that there was some degree of urgency about producing this report because various local authorities were making their own arrangements. The Ministry had met them in many respects and they got what they thought was quite a good interim arrangement, but they had made it quite clear that the figures would have to be reviewed after the revised scales for doctors employed part-time by local authorities (discussed on the previous day) had been considered and approved. The whole subject would have to come up for revision, but it was quite good for an interim arrangement.

The Brighton amendment was carried.

"BRITISH MEDICAL JOURNAL"

Dr. O. C. CARTER (chairman of the Journal Committee) presented the report under "British Medical Journal." He said that the first year's activity since the cessation of hostilities had been completed, and he could report to the Representative Body that never before had the *Journal* been in so sound a position both scientifically and financially. During the whole period of the war the *Journal* appeared regularly week by week in spite of phenomenal difficulties of production. It was a fine achievement which reflected the greatest possible credit upon the Editor and all who worked with him. It might have been thought that twelve months after the end of the war their difficulties would have disappeared. That was not so. It was true that staffing troubles had been considerably eased, and in this connexion he wished to say how pleased they were to see back amongst them the Assistant Editor Dr. Harvey Flaek, after a long period of war service (Applause.) But they were still faced with the difficult problem of acute shortage of paper, and with the increased circulation of the *Journal* this became more and more severe for the ration was not based on present-day circulation but on pre-war consumption. In 1939 the circulation was 42,000; last year it went up to 51,000, and the latest figure was 58,000. Therefore the problem of having to deal with rival claims for *Journal* space was no small one. But the present *Journal* of 68 pages was a very fair and well balanced production. The standard of articles had been maintained at a very high level. He had heard it said that some of these articles were not of immediate interest to general practitioners. But the function of the *Journal* was to see that all that was best in British medicine appeared between its covers; and bearing in mind the fact that the *Journal* had to cater for every type of practitioner, and that to a large extent the standing and reputation of the profession was sustained by the tone and temper of the *Journal* and the excellence of its matter, he thought it would be generally agreed that it had very ably fulfilled its role (Applause.) Before the war little was heard abroad of British medicine, but now it was looked to for a lead, and, as far as the *Journal* could give it, such looking would not be vain.

At the same time the needs of the busy general practitioner had not been forgotten. "Any Questions?" was started by the man who did not have a great deal of leisure for reading and this feature had proved enormously popular. Its answer to current problems which confronted doctors all over the world was becoming a weekly guide to medicine. On the medical political side there had been more activity than ever. Many leading articles on medico-political matters had appeared. The *Supplement* had contained the report of the Spens Committee and much other matter of immediate interest and concern. The debates on the National Health Service Bill had been fully reported. To make medico-political reading more attractive change had been made from treble column to double column and the size of type increased.

New Ventures

They were now (Dr. Carter continued) embarking on new features which were going to absorb a very considerable expenditure. During the last few years the number of speciality journals had increased, and now they had planned an Abstracting Service of the world's medical literature. Before the war abstracting service functioned in Germany; this had now ceased and it was intended that this new organization should fill the void thus created. Although, in the first instance, the intention was to provide information for the British medical practitioner it was equally planned as a contribution to world medical literature. It was proposed to publish two journals, one to be called *Abstracts of World Medicine* and the other *Abstracts of World Surgery, Obstetrics, and Gynaecology*. In June, 1944 he convened an informal conference on medical abstracting the outcome of which was a unanimous agreement that a comprehensive medical abstracting service in English was desirable. After nine months of spade work a scheme was placed before the Council and approved. This new venture would be the direct responsibility of the Editor of the *Journal* but additional staff, both medical and non-medical, had been

aged, and they had been extremely fortunate in securing Editor of the *Abstracts* Dr. G. W. M. Findlay, who had been connected for many years with the scientific work of the Ilkome Research Institution. They felt that they had got the finest possible man for the job; he would have very able assistants.

The Editorship of the "British Medical Journal"

Dr. Carter closed by referring with very great regret to the pending retirement of their distinguished Editor of the *Journal*, Dr. N. G. Horner. Dr. Horner had occupied the editorial chair since 1928, and for eleven years previous to that he was Assistant Editor. He had filled the position with great distinction and ability, and they all hoped that in the near future of his retirement he would find renewed health and strength. The speaker suggested that from that meeting an expression of appreciation should be sent to Dr. Horner. The meeting signified by acclamation its desire that this should be done.

It was with the greatest possible pleasure (Dr. Carter continued) that the Council had appointed Dr. Hugh Clegg Editor of the *Journal* as from January 1, 1947. (Applause.) Dr. Clegg had been for many years Deputy Editor. It was largely owing

to Dr. Clegg's initiative that the various quarterly special *Journals* had been established. These *Journals* attracted into the work of the Association medical men and women of high academic status who were not interested in medical politics but who by coming into the Association gave it added strength and completed its unity. It was also on Dr. Clegg's inspiration that the abstracting service had come into being. Without his help and advice and hard work during the last nine months the scheme would not have matured, and the credit for such a scheme would have gone to some body other than the Association.

Dr. J. A. BROWN (Birmingham) moved a resolution to press for a further supply of paper for the immediate publication of the selection of "Any Questions?" This was seconded by Dr. A. BEAUCHAMP. Dr. CARTER explained that the Association had been met rather handsomely in the matter of paper for *Abstracts*, and it would be difficult to go again immediately to the Ministry of Supply for more paper for another purpose; but if the request could remain in the hands of the Council to be used at a suitable opportunity as expressing the view of the Representative Body he would accept it on the Council's behalf.

The motion was agreed to on that understanding.

Dr. G. DE SWIET (Paddington) urged that there should be more authoritative regular articles on recent advances in the treatment of disease. While they appreciated the value of the more scientific articles, they were not quite what the busy practitioner wanted to read.

Dr. CARTER said that the *Journal* could not be made wholly of general practitioner interest. It was necessary to plan the space for all the various interests represented in the profession. But he hoped the time might not be distant when they could accept and put into practice the intention of the Paddington proposal; he could not accept it forthwith as an instruction.

The Paddington proposal was adopted, and the report under *Journal* was approved.

MEDICAL ETHICS

Dr. N. E. WATERFIELD, chairman of the Central Ethical Committee, presented the report under "Medical Ethics." He referred briefly to the arrangements made with the British Dental Association concerning selection of anaesthetists.

"Important Notice" Appointments

Dr. R. FORBES (Hendon) moved:

That the Representative Body is of opinion (1) that the Central Ethical Committee should have the exclusive power and duty to initiate action against any member who accepts an appointment that was the subject of an "Important Notice" at the time of its acceptance; (2) that the acceptance of a prohibited appointment shall be construed as prima facie evidence of an ethical offence justifying expulsion from the Association; (3) that the member concerned shall be afforded full opportunity to offer explanations to the Central Ethical Committee for his action or to present in argument any extenuating circumstances that appear to him to

apply to the case; further that the Council be requested to regard such action by the Central Ethical Committee as separate and apart from the investigations that are conducted under the existing Ethical Rules, and (4) that in respect of this new power vesting in the Central Ethical Committee, the Council be requested to prepare a report thereon together with the rules of procedure for presentation to the next meeting of the Representative Body.

As a member of the Ethical Committee he had been conscious of various difficulties which arose when action had to be initiated locally with respect to some member who had offended against the declared policy of the Association. He felt that it was necessary to improve the machinery for dealing with those who accepted prohibited appointments. It might be found that appointments were offered under terms and conditions which were wholly unacceptable to the profession, and it was all the more necessary that the machinery for dealing quickly and adequately with any offending member should work smoothly and efficiently. It usually fell to the local secretary to carry out the procedure, with the assistance of the central office, but that duty was so exacting and responsible that it might well be carried out centrally. The mere fact of acceptance of such appointments should be taken as prima facie evidence of the fault on the part of the member concerned, and the onus of proving failure to observe the policy of the Association should not rest solely with the Association. The person who had presumably offended should be required to satisfy the investigating ethical committee that he had not deliberately broken the Association's rules. He should, of course, be given every opportunity of appearing before the investigating committee. In conclusion Dr. Forbes asked for general approval only of these suggestions and that the Council should make a report on the subject.

Dr. A. V. RUSSELL (South Staffordshire) moved as an amendment that to subsection (2) of the Hendon resolution should be added the words—

"and that similar action be taken against any member who accepts an invitation to serve on any administrative or advisory body set up under the new National Health Service until such time as the majority opinion of the profession is known."

This was an ethical point of the utmost importance. Refusal to insert such words would convey an impression that the Representative Meeting was in favour of, or indifferent to, the acceptance by members of the Ministry's invitation.

Dr. FORBES hoped that the meeting would not accept this amendment. The motion by Hendon would by implication include all appointments which were inserted in the "Important Notices" column of the *Journal*. If the Ethical Committee considered that a particular appointment or series of appointments was worthy of insertion in that column it would appear there in due course. It would be impolitic and undesirable to go so far as to compass within this motion the terms and conditions of some new service not yet available. He had in mind something much more limited and more constructive than the South Staffordshire amendment.

Dr. J. A. PRIDHAM (Dorset) said that he was not quite happy about the Hendon amendment. The Central Ethical Committee was asking for the transference to itself exclusively of this duty of initiating action. Why take it away from a Division which might be quite capable of dealing with the matter? Moreover, it seemed to be assumed that the practitioner was guilty before he was heard. The onus of proof was on the practitioner to prove his innocence instead of, as in British courts, on the prosecution to prove the guilt of an alleged offender.

Appointments under National Health Service Act

Dr. A. V. RUSSELL at this point proposed the suspension of standing orders in order to admit of the South Staffordshire amendment being put forward as a separate motion. This was seconded by Dr. N. J. COCHRAN (Burton-on-Trent).

A three-fourths majority was required for such suspension, but this was not obtained, 83 voting in favour and 32 against. The South Staffordshire proposal continued to be discussed as an amendment to the Hendon motion.

Dr. J. C. ARTHUR (Gateshead) said that they had to take the facts of the situation as they found them, and having regard to all the facts he thought the amendment a most dangerous one. The meeting was being asked virtually to reopen all the contentious matters which it had considered on the previous

day. If the Minister set out to appoint Regional Boards and it should happen that the profession cared to work on Regional Boards, what sort of people did they want to go on them? They wanted people whom they could trust. In any case he begged the meeting not to tie itself down rigidly without adequate consideration.

Dr. T. M. ROSE (Preston) hoped that the meeting would have nothing to do with this amendment. "If you wish to destroy the influence of the Association and to fill these posts with quislings, then let the amendment be carried."

Mr. C. E. BEARE (Reigate) supported the amendment. "We cannot run the risk of people joining these boards now."

Dr. F. GRAY (Wandsworth) said that the meeting on the previous day had taken certain decisions and was now faced with the possibility of those decisions being got round and made useless. If members were allowed to take up these appointments on one pretext or another the position would be given away completely.

Dr. R. W. COCKSHUT (Hendon) said that they looked with disfavour on any person accepting office in certain circumstances. One representative, who had already left the meeting, had said that he expected to be invited to be a member of a regional body and he was going to accept. If the amendment were passed in its present form as an amendment to the Hendon motion it would mean that any man who accepted office would be put through the disciplinary machinery of the Association. But the Representative Body should express the opinion that no man should accept office on any of these committees. As the issue now appeared more clearly before the meeting, he suggested that another motion for the suspension of standing orders be taken, again with a view to the South Staffordshire amendment being taken as a separate motion.

The motion to suspend standing orders was then put a second time and received the necessary majority. There voted: in favour, 91; against, 23.

Dr. COCKSHUT then proposed and Mr. LAWRENCE ABEL seconded:

That in the view of this Representative Meeting no registered medical practitioner should accept membership of any committee or board established under the National Health Service Act until the results of the forthcoming plebiscite are available.

This was carried by a large majority.

Dr. WATERFIELD, on the Hendon motion, said that it meant a change of policy of the Association, limiting considerably the autonomy of Divisions, and although he was very much in sympathy with it he thought the only action the meeting could take was to refer it to Council for consideration and bring the matter forward at the next A.R.M.

Dr. FORBES said that the motion would merely record the opinion of the meeting. He saw no need to adopt the device of referring it to Council.

The Hendon motion was carried.

NAVAL AND MILITARY

Col. A. H. PROCTOR, chairman of the Naval and Military Committee, introduced the part of the report headed "Naval Military." He mentioned one or two additional items. New rates of pay had been introduced in the Army and all services now received the same rates of pay for corresponding rank. The new rates of pay were a considerable advance on the old. New rates of retired pay for officers recently retired had been introduced. Short service commissions were being offered to specialists.

Dr. J. A. GORSKY (Westminster and Holborn) moved: "That the meeting does not regard the release from the Services as satisfactory, and considers that establishments are overstaffed." He gave several instances of alleged excess. At an R.A.F. station in Shropshire, with about 2,500 personnel, there was a hospital of 186 beds. A few weeks ago it had just over 50 patients, and it was by no means certain that all the 50 were hospital cases. At this station there were 10 R.A.F. doctors.

Dr. G. DE SWIET (Paddington) supported the motion.

Col. PROCTOR said that the motion raised difficult questions. In every case where alleged overstaffing of hospitals had been brought forward the Army had been ready to investigate the

case. But in dealing with these complaints of overstaf certain factors had to be taken into account. There was, example, the question of fairness to the men serving over-s The present method of demobilization by taking into acco both length of service and age was the fairest. If it was clai that because a man was not fit to go over-seas he sho therefore be demobilized it would lead them down a slip slope.

The Westminster and Holborn motion was carried.

FINANCE

The TREASURER (Dr. Bone), in presenting the financial st ment, said that the assets of the Association were in an exce ingly flourishing condition. The Headquarters building taken into the accounts at £360,000, but it was probably w twice that. Investments represented something like £120, Subscriptions had reached a maximum figure, and the ince generally was satisfactory. He commented on the very succ ful financial aspect of the *Journal*. It was quite certain t the revenue of the Association would increase substanti again during the present year. He wished to remind rep sentatives, however, of the Association's heavy commitme These included:

- The necessary expenditure over the National Health Service Regional activities.
- The increase (to six) of the number of medical secretaries.
- The abstracting service.
- The fostering of international relationships.
- Building commitments. (These amounted to £70,000.)
- Extension of the library, with its sacrifice of outside rentals.

It was evident, therefore, that the funds of the Associati built up so well during these six "idle" years, should not wasted. (Applause.)

Dr. JANET AITKEN presented the report under "Medi Benevolence," which showed that a sum of £7,160 received during 1945 by the Charities Trust Fund, an incre of nearly £300 on the sum received in 1944.

Dr. GREGG presented the report under "Protection Practices" and called attention to the appendix to Supplementary Report of Council, published in *Supplement* of June 22.

SCOTLAND AND WALES

Dr. G. MACFEAT presented the report under "Scotland," drew attention to what was stated in the report about working of the Maternity Services (Scotland) Act, and a mentioned that a National Health Service Bill for Scotla would probably come before Parliament in October.

Dr. H. R. FREDERICK, chairman of the Welsh Committee, presenting the report under "Wales," said that this was first time for many years that the Welsh Committee had be able to submit a report. The committee had considered position of the hospital services in the Principality in relati to the administrative proposals of the Health Service B The result of its deliberations was set out in the report.

ELECTIONS

During the course of the meeting the following electi results were announced:

Chairman of Representative Body: Dr. J. B. Miller (no conte)
Deputy Chairman: Dr. E. A. Gregg (no contest).

Twelve members of Council elected by grouped representati (the figures denote the groups) (1) Dr. Vaughan Jones, (2) Mr. R. Newell, (3) Mr. A. S. Gough, (4) Dr. S. Wand, (5) Dr. H. Frederick, (6) Mr. Dickson Wright, (7) Dr. R. W. Cockshut, Dr. O. C. Carter, (9) Dr. A. Talbot Rogers, (10) Mr. I. Sims Hall, (11) Dr. W. D. Frew, (12) Dr. J. M. Hunter. (Contest only Group (9).)

Eight members of Council elected by the representatives acti together: Mr. Lawrence Abel, Dr. J. C. Arthur, Mr. A. H. Burge Dr. W. E. Dornan, Dr. R. Forbes, Dr. Peter Macdonald, Dr. Smith Pool, Dr. W. D. Steel.

Representative of Royal Naval Medical Service on Council (Council's recommendation): Surgeon Rear-Admiral W. H. Edg

On the proposition of Dr. I. G. Innes a hearty vote of than was accorded to the Chairman and Deputy Chairman, and th meeting terminated at 4 p.m.

BRITISH MEDICAL ASSOCIATION

114th Annual General Meeting

The 114th Annual General Meeting of the British Medical Association was held in the Great Hall of B.M.A. House, London, on Wednesday, July 24, 1946. Mr. H. S. Souttar, retiring President, occupied the Chair at the beginning of the meeting. The notice of meeting was read by the Secretary, and the minutes of the previous Annual General Meeting, published in the *Supplement* of August 11, 1945, were confirmed.

Induction of New President

Mr. Souttar then inducted into the Chair as President, 1946-7, Sir Hugh Lett, Bart., C.B.E., D.C.L., F.R.C.S., and invested him with the presidential badge of office. In doing so he described Sir Hugh Lett as his old teacher and colleague, a former President of the Royal College of Surgeons, Master of the Society of Apothecaries, and President of the Hunterian Society, and still Hon. Secretary of the King Edward Fund. Sir Hugh Lett had behind him a great experience of public service carried on in so quiet and unobtrusive a manner that it had not attracted the attention it really deserved. The Association was fortunate in having him as President.

Sir Hugh Lett said that he was deeply conscious of the honour done to him—an honour enhanced by the fact that he had been installed by his old friend and colleague Mr. Souttar, with whom he had worked in so many places over so many years, always with great advantage from his counsel.

Presentation of Stewart Prize

The President then presented the Stewart Prize, established for the recognition and promotion of research into the origin, spread, and prevention of epidemic disease, consisting of a certificate and a cheque for £50. There were two recipients—namely, Prof. Major Greenwood of the London School of Hygiene and Tropical Medicine, in recognition of his outstanding contributions, over a period of many years, to the science of epidemiology and vital statistics, and Dr. W. N. Pickles, of Aysgarth, Yorkshire, for his researches in the field of epidemiology which provided a close determination of the range of the incubation period of epidemic catarrhal jaundice and threw light upon epidemic myalgia (Bornholm disease), and was a model for research workers in general medical practice.

In presenting the prize to Prof. Greenwood the President said that it was impossible to over-emphasize the need there was for this valuable work. Under Prof. Greenwood's guidance statistics could no longer be accused of being able to prove anything. He had brought order out of chaos. To Dr. Pickles he said that it was with special pleasure that the Association had decided to award this prize to him because of all that he had done whilst engaged in a busy practice extending over a wide area of the dales of Yorkshire. It reminded one of the great work of Sir James Mackenzie on cardiac disease, carried out whilst he, too, was in the middle of a busy practice.

President's Address

The President then delivered a short address from the Chair. The address is printed in the opening pages of the *Journal*.

Appointment of Auditors

On the motion of Dr. R. Cove Smith it was agreed: That Messrs. Price, Waterhouse and Co. be and they are hereby appointed auditors of the British Medical Association until the next Annual General Meeting at a remuneration of 300 guineas.

Vote of Thanks to Past President

The Chairman of Council (Dr. H. G. Dain) moved: That the hearty thanks of the Annual General Meeting of the Association be given to the retiring President for his services as President, 1945-6. He said that when, on the death of Lord Dawson, they were confronted with the need for electing another President, they had no difficulty in turning to Mr. Souttar. He had served the Association in many capacities. He had been both Chairman of Council and Chairman of the Representative Body, and it was a fitting crown on his work that he should be elected President. The motion was carried with acclamation.

Mr. Souttar said that it was a very rare distinction to have held all these great offices, but it was a memory that would remain with him for ever that he had worked in such a happy brotherhood.

HEARD AT HEADQUARTERS

The New President

Sir Hugh Lett, Bart., who was elected President of the Association at the beginning of the Annual Representative Meeting, is the eleventh Fellow of the Royal College of Surgeons of England to take that position during the present century. During the same period there have also been three presidents who were Fellows of the Royal College of Surgeons of Edinburgh. In the earlier part of the Association's history few surgeons were numbered among its presidents—only three in the first twenty-five years. Sir Hugh Lett is a former President of the Royal College, a past Master of the Society of Apothecaries, and he has been President of the Sections of Surgery and of Urology of the Royal Society of Medicine and of the Hunterian Society. He is himself the son of a medical man, and he married the daughter of Sir Buckston Browne. In many ways Sir Hugh Lett has been helpful to the Association in recent difficult years, and his election to the presidency will be heartily welcomed.

South African Affiliation

Proposals for affiliation with the Medical Association of South Africa have been considered by the Representative Body. Although the agreement entered into nearly twenty years ago has come to an end and the Medical Association of South Africa has achieved independence and self-government, there has been a strong desire for an affiliation relationship, similar to that obtaining between the B.M.A. and the Canadian Medical Association. One difference which is proposed, however, is that in South Africa there should be created a new class of membership whereby a member of the South African body may become an affiliated member of the B.M.A., not paying subscriptions, but entitled to attend (without voting) meetings of local units, as well as the annual scientific meetings, and to use the house and library, and have the help of the central staff. In accepting the proposals for affiliation the Federal Council in South Africa has assured the "parent body," as it calls it, of its keen desire to maintain this link of friendship and mutual understanding. A large number of South African members have retained their subscription to the *British Medical Journal*.

Cold Efficiency

Mr. Bevan's memorable utterance about expiring in the warm sympathy (and implied inefficiency) of the small voluntary hospital comes to mind in connexion with a case, particulars of which have been sent by one of the Division secretaries to the local M.P. A man had a 40% disability pension awarded him for what was said to be osteo-arthritis of the spine. He had been discharged from a military hospital where, according to his statement, no x-ray films were taken, but he had been given exercises and electrical treatment, which only aggravated the pain, and later he was put in a spinal jacket. The Division secretary who relates the incident took the man into the voluntary hospital in his small town, and as a result of x-ray examination it was found that his real trouble was spondylo-lithesis. He was referred to the large voluntary hospital in the county town, where the diagnosis was confirmed, and where they were perfectly ready to take in the man and to operate. But the local regional officer of the Ministry of Pensions had to be informed, with the result that the hospital arrangement was cancelled, and the man was admitted to a Ministry of Pensions hospital. Here again x-ray examination confirmed the diagnosis. Arrangements were made for operation, even down to shaving and preparing the skin, when the medical officer interviewed the patient on his bed and told him that it had been discovered that the disease for which they were to operate was not the disease for which he was in receipt of a disability pension, and therefore the matter must wait until the question had been settled. The man was sent home, where, at the time of telling, he had been for a fortnight, unable to work and suffering a certain amount of pain.

Correspondence

Demobilized Doctors

SIR.—Dr. C. G. Jones (July 13, p. 66) and "Ex-Service Assistant" (*Supplement*, July 13, p. 12) have certainly ventilated the views of many "Returning Doctors." After five or six years' comradeship among our colleagues in the Services, we come back to an England of pretty speeches and prosy pamphlets.

We were told that the country was crying out for doctors, yet I, and several of my contemporaries demobilized in January and February, have not yet found a job. I have applied for over a dozen assistantships, with only one reply (to say the post had been filled), and one registrarship, to which I have not yet had a reply, three months after the closing date.

I have been offered some half-dozen practices at the reasonable enough premium of one to one-and-a-half years' purchase, but with the proviso that the house must be sold with the practice. The house is useful, for our days of bivouacking are, I trust, over, but the price asked has invariably been 30-40% above current prices, and about 300% above pre-war prices. The vast majority of us, a year ago, would have had no truck with Mr. Bevan's "negative direction"; but better that, at a living wage, than the economic direction of our established fellows.

We ask no favours for doing our duty to the fighting man, indeed we are proud to have been of service, but let us have at least a chance to start again.—I am, etc.,

"UNEMPLOYED EX-SERVICEMAN."

Medical Unemployment

SIR.—I was rejected in 1939 for service in the armed Forces. During the war years I did four assistantships, and as everyone knows we were short of medical practitioners in general practice during that period. Last January 31 I was replaced by a returning partner from H.M. Forces. Since then I have failed to obtain work. Six months' enforced idleness. I have written the B.M.A., the Minister of Health, all the medical agencies, and roughly 600 letters in reply to announcements in the *British Medical Journal*. From these letters I have received less than 30 replies from courteous medical practitioners. We are at the moment employing somewhere about 1,000 alien doctors in this country. Is this the reward for working many many hard years of war work?—I am, etc.,

Treharris, Glam.

G. L. E. THOMAS.

Delayed Release of Specialists

SIR.—I would like to write a few words of encouragement to Service specialists and R.A.F. medical officers, who now fill these pages with their laments. Everyone, I am sure, sympathizes with the specialists in their delayed demobilization, but I hope they will remember that when their day does come, their war service will be of more account in getting jobs than that of their humbler colleagues. Many of these joined in the early days without even taking their M.B.s, let alone waiting for higher qualifications. Many of them have been on real active service in small ships, parachute regiments, invasion craft, and the like. To them the specialist's life and rank seemed a most desirable way of spending the war.

The mortality rate of surgeon-lieutenants, for example, in the dark period of the war was considerably higher than that of their better qualified contemporaries or companions in arms in the R.A.F. medical service. Let the psychiatric specialist rejoice that it was other people's nerves he dealt with so efficiently, and the specialist delight in the fact that it is more pleasant and intellectually satisfying to write an article on the treatment of large numbers of compound fractures, or immersion feet, than to be a mere participant. A few months' delay in demobilization that puts him level with the combatant officer is surely not too high a price to pay for these advantages.—I am, etc.,

EX-SERVICE MEDICAL OFFICER.

Association Notices

Meetings of Branches and Divisions

BATH DIVISION

A well-attended meeting was held on July 17 with Dr. G. STEVEN in the chair. The first item taken was the report of a subcommittee appointed to meet the medical officer of health to discuss the implementation of the Education Act, 1944. It was agreed that in view of the Ministry of Education's Circular No. 1946, it was impossible for a local authority to pay for the treatment of school children by their family doctor, but it was decided that the local authority medical officer when referring patients to their own doctor should state that "The education authority cannot be responsible for the payment of fees for the treatment of your child by Dr. —." Inside the envelope would be a form on which the local authority medical officer would enter a provisional diagnosis and other notes, and it was hoped that on the reverse of the form would be room for a reply from the doctor, who could get 5s. for each report.

The meeting then discussed the position of ex-service medical officers and passed the following resolution: "That the Council of the Association be informed of the alarm felt by this Division concerning the position of practitioners and specialists returning from service with the Forces with particular reference to the continued employment of aliens in paid appointments."

POSTGRADUATE NEWS

The Fellowship of Medicine announces that there will be a week-end course in chronic rheumatism at Royal National Hospital for Rheumatic Diseases, Bath (in association with the University of Bristol) on Friday afternoon, and all Saturday and Sunday, August 23, 24, and 25.

APPOINTMENTS

BEHRMAN, SIMON, M.R.C.S., M.R.C.P., Honorary Neurologist, Queen Mary Hospital for the East End, Stratford.

CARDIFF ROYAL INFIRMARY.—Honorary appointments. Assistant Surgeon Ear, Nose, and Throat Department, H. A. Thomas, F.R.C.S.Ed., Assistant Physician specializing in Neurology, J. D. Spillane, M.D., Assistant Physician (General Medicine), B. Evans, M.D., Assistant Surgeon specializing in Urology, R. A. Moss, F.R.C.S., Surgeon in charge of Fracture and Orthopaedic Department, D. Evans, F.R.C.S.Ed., Dermatologist, G. A. Hodgson, D.M.

CLARK, J. M. P., F.R.C.S., Honorary Assistant Orthopaedic Surgeon General Infirmary at Leeds.

COOPER, H. ASTLEY, M.D., M.R.C.P., D.P.M., Senior Physician, Rush Hospital, Wickford, Essex.

MIDDLESEX HOSPITAL, W.—Assistant Physicians: A. Wilcox, M.D., M.R.C. Assistant Surgeon: C. J. B. Murray, M.S., F.R.C.S., Assistant Orthopaedic Surgeon: P. H. Newman, F.R.C.S., Anaesthetist: O. P. Dinick, M.B.S., D.A.

PAYTON, C. G., M.D., D.P.H., Medical Officer of Health and School Medical Officer, etc., County Borough of Northampton.

ST. GEORGE'S HOSPITAL, S.W.—Assistant Physicians: M. T. A. Hun, M.D., M.R.C.P., J. F. Dow, M.R.C.P., Assistant Neurologist: Denis Williams, M.D., F.R.C.P., Assistant Surgeons: A. M. H. Siddons, M.Chir., F.R.C. Rodney Smith, M.S., F.R.C.S., Director of Pathology (whole-time post), T. Crawford, M.D.

SOUTHAMPTON: ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Honorary appointments. Physician, K. M. Robertson, M.D., Orthopaedic Surgeon, H. H. Langston, F.R.C.S., Ophthalmic Surgeon, E. Zorab, M.B., B.D.O.M.S., Dermatologist, F. J. Egar, L.R.C.P.S.I., Assistant Physician, H. K. Meller, M.R.C.P., P. G. Todd, M.D., Assistant Surgeon, L. Richardson, F.R.C.S., Assistant Anaesthetist, H. Oakley White, M.R.C.L.R.C.P.

UNIVERSITY OF LONDON: INSTITUTE OF CHILD HEALTH.—Assistants to Professor of Child Health: R. S. Illingworth, M.D., D.C.H., R. E. Bonhag, M.B., B.Chir., M.R.C.P., Part-time Lecturer in Genetics: J. A. Frazer, D.Sc., M.D., M.R.C.P.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BRADFORD.—On July 13, 1946, at 10, Victoria Park, Liverpool, 15, to Mr. (née Roberts), and Dr. W. E. Gerald Bradford, a daughter.

LISTER.—On July 18, 1946, at 549, Alexandra Parade, Glasgow, to Mr. M.A., and James A. Lister, M.B., a daughter—Jean Graeme.

SMITH.—On July 22, 1946, at 18, Colin Gardens, N.W.9, to Betty (Gilbert), wife of Brian J. Douglas Smith, M.B., B.S.Lond., a son—Nicholas.

MARRIAGES

COLQUHOUN-MEYER.—On July 3, 1946, at Kuala Lumpur, Malaya, Squ Ldr. John Colquhoun, R.A.F.V.R., of Nottingham, to Emelia Meyer, Voorburg, Holland.

DUGUID-BARRY.—On July 6, 1946, at Wallasey, Cheshire, John Duguid, M.B., Ch.B. (Major, R.A.M.C.), to Aileen Mary Barry, M.B., Ch.B.

DEATH

GEMMILL.—On July 28, 1946, at 27, Woodbourne Road, Edgbaston, Birmingham, William Gemmill, M.A., M.B., Ch.M., F.R.C.S., Professor of Surgery Birmingham University, dearly loved husband of Janet Gemmill.

MALE INFERTILITY*

BY

T. N. A. JEFFCOATE, M.D., F.R.C.S.Ed., F.R.C.O.G.

(From the Department of Obstetrics and Gynaecology in the University of Liverpool)

ough it has been known for centuries that the unfruitfulness of some marriages is due to a fault in the male rather than the female partner, only within the last few years has male fertility received the attention it merits. Even now its importance is not always appreciated by members of our profession, let alone the public. Some men, particularly of hospital class, refuse any sort of investigation, and for reasons which are now well known—ignorance, embarrassment, religious scruples, fear of loss of male prestige, etc. It is not rare for the wife to object to her husband being examined, either because she is afraid of the effect that knowledge of his infertility may have on their relationship, or because she believes that male infertility cannot be treated successfully and she prefers to live in hope rather than know the truth. Some doctors explain their omission to test the husband on the ground that the discovery of the infertility will have a bad psychological effect and create unhappiness. There may be grounds for this view in the isolated case, but in general it seems an excuse rather than an adequate reason. Great care is necessary in disclosing the cause of their infertility to any couple, and even then it must be admitted that unforeseen reactions disturbing the harmony of marriage sometimes occur. What is said to the couple will vary with individual cases, and prognosis should err on the side of optimism. Often it is best not to tell the whole truth, particularly to men afflicted with impotence, lest their self-confidence be further weakened.

For the purpose of this paper a series of 512 consecutive cases of sterility seen in private practice and personally investigated have been analysed. Also, for comparison, an analysis of 283 consecutive cases seen over a short period in hospital practice is also included. The findings are those of routine clinical practice and do not in any way represent the results of a special investigation. The majority of the cases were dealt with during the war years, when laboratory and x-ray facilities were limited and when many husbands were away from home for longer or shorter periods. All the cases were investigated not less than one year before this review, and the post-natal history is known in all except 67. An honest attempt was made to examine the husband in every case except those in which the wife had symptoms additional to the sterility and investigation of the latter became incidental to the treatment of the cause of the former. Of the 512 private cases only 491 were investigated, and out of these some sort of assessment of the husband's fertility was made in 320. In the hospital series the husband's fertility was assessed in 115 of the 252 cases investigated.

The first question which arises, and one which is always being asked, is, "How often is the male partner responsible for infertility marriage?"

It is difficult if not impossible to give a concise answer to this—or, indeed, to form any exact estimate, and for the following reasons:

1. Fertility, either of the individual man or woman or of a marriage, is a matter of relativity. Comparatively few people are absolutely sterile or fully fertile. All intermediate grades of fertility occur in either sex, and the fruitfulness of a marriage is dependent on the summation of the fertility of the two partners. If there is no absolute bar to conception on either side, low fertility in one partner may be cancelled out by high fertility in the other.

2. In a large proportion of cases infertility results not from one but from several factors, which may be distributed between the two partners. The average number of such factors per case is variously assessed as between 2.23 and 4.75 (Hamblen, 1945). Thus, for example, the wife may have a cervical erosion and a uterine retroflexion, whilst the husband's production of spermatozoa may be subnormal as regards both number and quality. Who is to say which factor is the most important or indeed which partner is chiefly to blame? Scientifically, therefore, a statement of the cause of childlessness in any marriage should consist in a listing of all the infertility factors present. Treatment should aim at the elimination of as many of the infertility factors as possible.

3. The assessment of male fertility is in itself difficult.

(a) *Procreation Test.*—Perhaps the best test is whether a man can procreate children, and there are many cases in which it is known that the husband has had a child by another woman or by the wife. Sterility following one or more pregnancies is common, and in such cases there is a natural tendency to exonerate the husband from blame—on the ground that he has proved his fertility. If a man has been responsible for several pregnancies then it is reasonably certain that his fertility is within normal limits unless circumstances which might have affected it have arisen since the last pregnancy. If, however, he has been responsible for only one pregnancy, it is by no means proof that his fertility is up to average standards, and it is not difficult to produce many cases showing that, although a man has procreated once, his fertility is so low that the chances of his repeating the performance are remote. In this series there were 181 women complaining of infertility after one or more pregnancies, although 10 must be excluded because the man responsible for the pregnancy was not the husband. It will be seen from Table I that when the wife had had one abortion 11 out of the 25 husbands tested had impaired fertility—in one case azoospermia on two tests. When the women had had one child 13 out of 33 husbands were proved at fault. It should be kept in mind, however, that the husband was tested in only about one-third of the cases. In many of the others some gross abnormality, such as occluded or damaged tubes, was found in the wife, and the chances are that the husband in those cases was normal. Nevertheless, comparable figures are published in the literature (Lane-Roberts *et al.*, 1939). There are several explanations for such findings. Sometimes the husband has had an illness or injury since the date of the previous pregnancies: in two of these cases mumps had occurred, but in

*An abridged form of papers presented to the Liverpool Medical Institution on March 1, 1945, and the Birkenhead Medical Society March 8, 1946.

only one of them was there a history of orchitis. Sometimes spermatogenesis fails or deteriorates without any apparent reason at a comparatively early age. The usual explanation, however, appears to be that the husband had always been subfertile and the occurrence of the one pregnancy with no subsequent ones depended entirely on the laws of chance.

TABLE I.—*Relative Infertility*

Total no. of cases	181
No. of cases in which present husband was not the father ..	10
Husband not tested	6
" proved normal	2
" proved to have azoospermia	2
No. in present series	171

	No.	Husband Examined	No. with Male Fault
One abortion only	50	25	11 (a)
One child only	83	33	13 (b)
More than one pregnancy ..	34	6	0
Ectopic pregnancy only	4	1	0
Total	171	65	24

(a) One case showed azoospermia to two tests.

(b) Intercurrent disease (mumps) in two cases.

(b) *Clinical Examination.*—Routine examination of the male, from both the standpoint of general health and the conditions of the sex organs, is clearly required—as are the details of the past history of any disease which might have affected genital function. Knowledge of the sex life of the individual, frequency of coitus, etc., is also helpful. However, physical examination of the male is of strictly limited value: if the findings are positive—e.g., atrophied testes—then they are significant, but if the findings are negative no conclusion is possible. In this series only about one-quarter of the husbands were interviewed and examined, and only five of these belonged to the hospital class. The remainder were not seen either because they refused or because they were not available for reasons of national service. However, the wives were always questioned as to the age, occupation, general health, and previous illness of their partners. The relationship between the clinical findings and male fertility as assessed by semen analysis is shown in Table II. The

TABLE II.—*Clinical Features as Compared with Semen Analysis*

Cases					
A. Husband not examined physically, but no significant history obtained via wife					
Semen normal					147 cases
Gross infertility					43 "
Minor infertility					51 "
No semen test					289 "
B. Husband examined or history of significant ill-health obtained via wife					
					208

Findings on Clinical Examination	No. of Cases	Normal Semen	Gross Infert.	Minor Infert.	Semen not Tested
Normal genitalia { No significant history ..	132	95	10	16	11
{ Impotence ..	14	1	1	2	10
{ History of a mild mumps ..	1	—	1	—	—
{ History of G.C. ..	5	2	2	—	1
Bilateral testicular atrophy or hypoplasia. (Various causes: impotence as well in 2 cases)	26	2	17	3	4
Unilateral testicular atrophy or hypoplasia	7	1	3	3	—
Varicocele without testicular atrophy	7	2	2	3	—
Phimosis	1	1	—	—	—
Not examined { History of orchitis ..	1	—	—	—	1
{ History of G.C. ..	3	1	2	—	—
{ History of adult mumps ..	4	2	1	—	1
{ History of syphilis ..	1	—	—	—	1
{ Age over 60 ..	2	1	—	—	1
{ History of severe general disease—e.g. phthisis ..	4	—	1	3	—

figures here bear out the general contention that genital abnormalities recognizable on routine examination nearly always mean impaired fertility, but they also show that of 132 men who had a good past history and apparently normal genitalia 26 had lowered fertility, often of serious degree.

(c) *Semen Analysis.*—Male fertility is mainly assessed by semen analysis. Semenology is now occupying the attention of a good many research workers in several countries, and it may ultimately be found that an exhaustive examination of the various characteristics of both fluid and cellular contents is necessary before any conclusion can be drawn in any given case. At present, and for practical purposes, the least information that is required about any specimen

concerns particulars as to the volume of the fluid, the number, spermatozoa, their motility, their survival capacity, and morphology. In assessing any one specimen all these features should be considered in relation to each other rather than separately. Examination of a single specimen in any one case is probably sufficient, since semen does show spontaneous variations, particularly in some individuals. In this series examinations were carried on semen collected by masturbation into a glass container transported at atmospheric temperature. The test was usually repeated when the findings were abnormal.

The interpretation of semen analysis demands some critical of what is normal or at least within normal range, and difficulty arises. Reference to this will be made later, but criteria used in connexion with these cases have been: (a) Volume of fluid was accepted as abnormal only if it was repeatedly less than 0.5 ml., or if the sperm density was low, making the total population of the specimen less than millions. (b) Number of spermatozoa. With the above exception, no count above 30 millions per ml. was accepted outside the range of average fertility. (c) Motility. W. specimens were suitable for motility examinations, asthenozoospermia was diagnosed only if there were less than 40% motile at the end of six to eight hours. (d) Morphology. Semen not regarded as subfertile unless more than 50% of spermatozoa were found malformed. The observations confirm those of others—namely, that the greatest number of morphological faults are mostly seen when the sperm count is low; partly for convenience, and partly because experience goes to show that sperm density is the most important single criterion. The findings are classified under the headings of number, spermatozoa rather than according to their morphology. With the sperm count was found to be 10 million per ml. or less it was taken to mean serious impairment of fertility. All other types of seminal faults are classified as indicating moderate impairment only.

Of the total of 743 infertile marriages investigated, semen analysis was carried out in 424. In 108 cases, however, the details are not available, because the pathologist of one hospital, although indicating significant departures from the normal when they were encountered, otherwise reported the number, motility, and morphology of spermatozoa as being "within normal limits." This was accepted at the time, but it is not satisfactory, and it may have resulted in the omission of some cases of impairment of fertility. Another 5 tests were carried out elsewhere, and the results could be obtained only through the wife, who described them as being reported to her as "not satisfactory." It is to be regretted that with few exceptions it was impossible to take steps to distinguish between seminal abnormalities due to faulty spermatogenesis and those due to an obstruction in the path of exit of the spermatozoa.

The findings are set out in Table III, from which it will be seen that in the private series the husband alone was at fault

TABLE III

Private series	Total no.	512
	No. investigated	491
Hospital series	Total no.	283
	No. investigated	252

Main Causes of Infertility	Private Series		Hospital Series	
	No.	%	No.	%
Fault in wife (husband normal)	152	31.0	46	18.2
Fault in wife (husband's fertility not investigated)	139	28.3	107	42.4
Fault in husband (wife normal)	72	16.7	30	11.5
Fault in husband (wife not investigated)	10	—	19	7.5
Fault in both husband and wife	52	10.6	—	—
No cause for infertility found	66	13.4	50	19.8
Both partners investigated	27	—	11	—
Only wife investigated	32	6.5	30	11.9
Only husband investigated	7	—	9	—
Total no. of husbands investigated	320	(Semen test in 309) (41.1%)	115	(Semen test in 111) (42.6%)
No. with lowered fertility	134	—	49	—

in about 16.7% of cases and that both partners were more or less equally at fault in about another 10.6%. It should be noted, however, that in the 28% in which an infertility factor (frequently a minor one such as acute antelexion of the cervix) was found in the woman the man was not tested. Furthermore

another 6.5% in which the husband's fertility was not assessed no abnormality at all was found in the wife, and in many of these it is highly probable that the husband, if he had been available, would have been found infertile. In some of these cases this is almost certain because there was suggestive evidence by way of past illnesses, or the wife was fertile to other men, etc. It seems fair to conclude that there is an important male infertility in about one-third of the cases, although in about one-third of these the wife too has some impairment of fertility. The findings in the hospital series are not so informative because a smaller proportion of husbands were investigated. So in only about 19% was a male fault found. There is little doubt that this figure would be much higher if more complete inquiry had been possible. This contention is borne out by the fact that in both series 40% of the husbands examined were found to be subfertile. These figures are confirmed by nearly all recent writers. Thus Siegler (1945) found a male fault in 47.9% of cases (combined with a female fault in 22.3%). Mazer and Israel (1941) say that at least 40% of husbands of infertile marriages can be shown to be at fault. Hamblen (1945) says that absolute sterility is due to male causes in 40-45% of cases—although he adds that fertility-reducing factors are present in over 90% of husbands of infertile partnerships. Sharman (1944) found that 31.6% of husbands tested had subnormal seminal fluid.

Fifteen per cent. of the marriages in this country (Registrar-General's Statistical Review, 1938) and in America are childless: involuntary sterility is present in not less than 10% of marriages, and is now mostly reckoned as occurring in one of every eight or nine couples (Hamblen, 1945). If we accept the conservative figure of 10% and admit that in not less than one in three infertile marriages the husband is wholly, or in large measure, responsible, then we can conclude that at least one in every 30 men who marry is either sterile or has considerably impaired fertility. That means that in England and Wales (the 1939 and 1940 figures) something like 15,000 to 16,000 subfertile men get married every year. These figures are so impressive, and child-bearing means so much to the happiness of the average woman, that there is something to be said not only for premarital physical examination of the man but for routine semen analysis. However, if premarital semen analysis is carried out it must be done efficiently and the results interpreted with caution. In this series are men of extremely low fertility who had previously been pronounced fully fertile on the finding of a few motile spermatozoa in a hanging-drop preparation. There are others in whom no fault was discovered who had elsewhere been diagnosed as infertile because spermatozoa in a condom specimen had been found amotile—a finding which is almost the rule.

Types of Male Infertility

The details of the types of male infertility in the 183 cases are set out in Table IV. Some would not include cases of

TABLE IV.—Details of 183 Cases of Male Infertility

Impotence (semen normal in 2; not examined in 11)	13
Phimosis preventing coitus (semen normal)	1
Faults in semen (impotence as well in 3 cases)	169
1. Low sperm density, etc.	137
Persistent azoospermia	38
Intermittent azoospermia	4
2 million or less per ml.	26
3-10 million per ml. (impotence in 1)	26
11-20 million per ml. (impotence in 2)	26
21-30 million per ml.	29
2. Low volume alone	2
3. Low volume with total sperm population less than 50 millions	3
4. More than 50% abnormalities	12
With asthenozoospermia	3
Without proved asthenozoospermia	5
With low volume	1
5. Necrozoospermia or asthenozoospermia	10
6. Semen "unsatisfactory"—probably azoospermia	5

impotence, but it should be pointed out that no such cases are included in this series except when the desire for children was the chief concern of both husband and wife. Impotence in varying degrees is probably more common than is generally supposed. In order that the balance of the series be not disturbed, apareunia due to conditions such as vaginismus is included under faults in the wife, but again only when sterility was the chief complaint. Thirty-eight men had azoospermia and another

four submitted specimens necessitates masturbation. Its best indication and at other times extreme, from some condition, organic or with 46 men with a sperm count—impotence—which interferes make up a total of 88 cases of serious—excellent treatment, Impotence of a child

Impotence is more often due to psychological disturbance than to any physical disability or endocrine upset. There was only one example of obvious endocrine disorder, and that pituitary infantilism. Nevertheless, in three out of the 16 cases (and the semen was examined in only five cases) there was definite evidence of defective spermatogenesis. In one case fertility was grossly subnormal and testicular atrophy following mumps was present. Even in these cases, however, there was a psychological factor which was probably important in the causation of the impotence. As a rule it was easy to elucidate the reasons for the men's inhibition: guilt over masturbation; a wrong outlook on sex resulting from misguided instruction from parents and others; religious zeal; an abnormal respect for the opposite sex; underlying desire not to have children—all were encountered. Some men could be described as effeminate or undersexed, but, contrary to the suggestion of Lane-Roberts *et al.* (1939), it was not only the latter who complained of the type of impotence in which erection and penetration are achieved but ejaculation never takes place. In one of the cases the husband developed secondary impotence because the wife wrongly accused him of sterility. The treatment of these cases consisted essentially in talks and discussions with the object of sorting out the underlying cause of the inhibition, explaining it, and giving instruction on sex matters. The wife was interviewed separately and instructed in the attitude she should adopt, the need for sympathetic encouragement and patience on her part being stressed. The wife was not always helpful, however, and any good she may have achieved was sometimes undone by an outburst which revealed her exasperation at the repeated failure of her husband's attempts. Testosterone, usually by the sublingual route, was also employed, but in the main proved ineffective. Even when it appeared to help it may well have been because the man was impressed by the idea of taking a glandular preparation.

The results of treatment of this series were as follows. Two men refused to co-operate or have any form of treatment. That leaves 14 who were treated both by interview and by discussion, and sometimes by testosterone—mainly administered by mouth. In five cases the ultimate effect is unknown. Of the other nine, three showed little improvement, while six were cured—four to the extent of proving their fertility by impregnating their wives. In one of the latter cases, however, the pregnancy resulted from artificial insemination and was ectopic in site.

Causes of Defects in Production or Delivery of Spermatozoa

1. *Mumps*.—Mumps occurring after puberty is always a potential menace to testicular function, at least so far as the production of spermatozoa is concerned. Ten men gave a history of having had this disease after the age of 14, but in one the seminal fluid was not examined. Of the nine examined six had either azoospermia or extreme oligozoospermia and teratozoospermia. Only two men are recorded as having a count within normal limits, and both of these were only 14 at the time they had mumps, and did not suffer from orchitis. One proved fertile. The remaining man had atrophy of one testis, and although the number of spermatozoa was low he achieved one pregnancy in seven years.

2. *Cryptorchidism*.—Late or non-descent of the testes is well known to affect spermatogenetic function adversely, probably because of the slightly higher temperature within the abdominal cavity. All four of the patients with bilateral cryptorchidism or giving a history of operation for such had azoospermia or extreme oligozoospermia. There were two other men in whom only one testis was undescended. The descent of the other may have been late, but details of this could not be obtained. Both showed moderate impairment of fertility. None of these six men has had children. Unless there has been operative treatment, or unless the testes have remained permanently above the scrotum, it is usually impossible to obtain from patients any information as to the age of descent. It may be that spon-

only one of them was there a history of spermatogenesis fails or deteriorates at a comparatively early age. The cause is to be that the husband has a history of the one pregnant woman, and on the laws of

These men showed azoospermia or oligospermia. The semen was normal in three. In another the fluid, and they probably had a child (subsequent to the gonorrhoea) by a woman. (b) *Syphilis*.—Only one man gave a history of syphilis, but he was not examined. Nevertheless he had a child. This case was interesting because the wife had had three husbands, each of whom had children by other women. Yet when she was examined no cause for infertility could be discovered.

4. *Varicocele*.—Nine men were found to have varicocele of significant size, and in two of these the testes were either hypoplastic or atrophied. It is impossible to say, however, whether the varicocele followed atrophy or whether it was primary and interfered with full development. In only two of these men was normal seminal fluid found; evidence of low fertility was present in all the others. Although no definite conclusion as to cause and effect is possible in these cases there seems little doubt that varicocele can interfere with testicular function—presumably by altering the temperature of the scrotum or the blood supply to the testis.

5. *Hormone Imbalance*.—When azoospermia or oligospermia is present there is often no obvious cause for it and the testes feel normal. On section it is said that the tubular apparatus shows areas of focal degeneration but that the interstitial tissue is unaffected (Hamblen, 1945), and this observation is supported by the fact that the man rarely shows signs of testicular hormone deficiency. The usual manifestations of pituitary disorder are not seen, and it is suggested that the fault is primarily in the testes, or, at any rate, that there is no deficiency in the gonadotrophic stimulus from the pituitary. Hypothyroidism appears to play some part at times, although there is little reason to suppose it has any direct action on the testis (Allen, 1939). One of the patients in this series with moderate impairment of fertility might have been regarded as showing a mild form of the dystrophia adiposa genitalis syndrome, and one as approaching giantism. A third was a typical case of pituitary infantilism, but he was impotent and no semen could be obtained for examination. In all the others physical development and secondary sex characteristics were within normal range. Basal metabolic rate estimations were not carried out.

6. *Sundry Causes*.—In isolated cases the following factors which might have affected spermatogenesis were encountered: a series of serious illnesses in childhood (1 case); orchitis following influenza (1 case); repeated exposure to x rays (1 case); history of bilateral hernia operation (2 cases); systemic disease such as malaria and phthisis (4 cases). One man had atrophy of one testis following injury, but produced good quality semen and subsequently had a child. There were no cases in which over-indulgence in coitus appeared to play any part—nor is there much evidence to support the view that it ever does lead to infertility. On the contrary, there were some cases in which the absence of children was at least partly explained by the infrequency of coitus.

7. *Causes Unknown*.—In about half the cases no cause was apparent, and this is the experience of most observers. In such, many possible aetiological factors have been postulated.

(a) *Nutritional Deficiencies in Childhood and Adolescence*.—As a result mainly of experiments on rats it has been suggested that inanition in general, and vitamin A, vitamin B₁, and vitamin E deficiencies in particular, lead to failure of spermatogenesis. Nevertheless there is little evidence to show that infertility in man is the result of a deficient diet, and the idea is not supported by the fact that errors in spermatogenesis are just as common in the middle and upper classes as in the more poorly fed lower classes, if not more common.

(b) *Heredity and Constitutional Factors*.—These may play some part in male fertility. They do in animals, and it has been shown that certain human families have a tendency to "die out." There is certainly, among patients, a widespread belief in inherited or familial infertility. Two sets of brothers, both suffering from azoospermia without obvious cause, were encountered in this series.

(c) *Occupation, Environment, etc.*—It has been stated that defective testicular function is more common in those of higher intelligence, or among brain workers, than in manual workers. It would probably be difficult to prove this, because, although the reproduction rate is higher in the labouring classes, this is almost certainly mainly the result of contraception practised in the higher grades of society. Nevertheless, there may be some truth in this idea, and clinical experience does give the impression that non-manual workers—those with responsibilities and anxieties—tend to be less fertile. The very nature of their work, usually necessitating long hours indoors and deprivation of sunlight and physical exercise, probably plays a part, as does the pace of modern life and the general stress and strain—nervous rather than physical. One of the conditions of modern life which may lower male fertility is the habit of taking frequent hot baths. The susceptibility of the testes and spermatozoa to even a moderate amount of heat is now generally accepted. Another consideration of interest, and possibly importance, is the failure of spermatogenesis which occurs with age. Many men remain fertile until advanced years, but in others testicular function seems to fail at a comparatively early age without any apparent ill-health to account for it. In one man, only 37 years of age, the sperm count gradually fell from 85 million to 17 million per ml. during the course of two years.

Finally, it should be kept in mind that in some cases of azoospermia and oligospermia in which the testes appear normal the lesion is an obstructive one in the epididymis, and not necessarily gonococcal in origin. A history of fleeting and mild non-specific epididymitis was elicited on close inquiry in two cases.

Treatment of Faulty Spermatogenesis

In the absence of an obvious cause the treatment of faulty production of spermatozoa is for the most part empirical. Attention to general health and habits, hours of work and recreation, etc., is always important, but, apart from this, some form of hormone therapy is usually advised. Many favour thyroid, but it was not used in this series, and serum gonadotrophin was the treatment of choice. This was given by intramuscular injections of 1,000 i.u., either twice weekly for three months or, in a few cases, daily for 10 days, and repeated after an interval. Vitamin E was given at the same time—although it is doubtful whether this is of any value, because experimental evidence goes to show that the effect of vitamin E deprivation on the testes cannot be reversed. The details of treatment and the results are known in 14 cases. Three of these 14 men have since produced children, and in one case the man, who was shown on two tests to have azoospermia, impregnated his wife almost immediately after the course of treatment was completed—and that after eight years of sterility. The sequence of events made it look as though the treatment was concerned in the pregnancy, but it is more likely to have been a coincidence. Comparison of the semen findings before and after treatment is of some interest, and the details are given in Table V. Case 11 is the one just referred to, and it is to be noted that semen examined nine months after the conclusion of the treatment (i.e., at the time of the birth of the child) again showed what almost amounts to azoospermia. Only two spermatozoa were found after prolonged search of wet and stained preparations of the centrifuged deposit. Opinions vary as to whether treatment with gonadotrophin does in fact improve spermatogenesis, but, with the exception of cases 4, 5, 10, and 11, the findings recorded in Table V seem to indicate that the quality of the semen improves after treatment and that it deteriorates again when treatment is suspended. These results, although suggestive, are not conclusive, and the possibility of spontaneous variations in the semen cannot be excluded.

Although there is some evidence to show that small amounts of testosterone may improve sperm production, it can be stated that, in general, the effect, at any rate of large amounts of testosterone, is a depressant one. Testosterone was not used in the treatment of any of these cases, and when it was given for impotence care was taken in the matter of dosage, particularly when the man was known to have defective spermatogenesis in addition to impotence.

Treatment of Obstructive Lesions in Male Genital Tract.—The appropriate treatment of a mechanical obstruction of the

epididymis or vas is some form of short-circuit operation. None of the cases in this series was so treated, and, judging from the literature, the operation is difficult and the results on the whole unsatisfactory. An alternative line of treatment which at first sight appears hopeful is to obtain spermatozoa by testicular puncture and to inject them into the vagina. This, however, is not satisfactory, because the spermatozoa as they leave the testis are immature and incapable of fertilization. They become fully matured only during their two-weeks journey through the epididymis and vas. And so it is stated (Halbrecht, 1944) that there is but one reported case of successful insemination with material taken from the testis.

Investigation and Treatment of the Wife.—If the wife should not be subjected to the investigation and treatment of infertility until the husband's fertility has been assessed, then equally there is much to be said for not subjecting the husband to treatment until there are good grounds for believing that the wife is reasonably fertile. Thus, in this series, 14 husbands with defective spermatogenesis had wives whose tubes were damaged (completely obstructed in 3 and partially obstructed—including unilateral occlusion—in 11). It may be added that

grounds—it usually necessitates masturbation. Its best indication is when the man suffers from some condition, organic or functional—e.g., hypospadias or impotence—which interferes with the act of coitus. For impotence it is excellent treatment, for the knowledge that he is fertile and the father of a child goes a long way towards restoring the man's confidence and self-esteem. Also, once pregnancy is achieved the necessity for coitus becomes less vital, and both husband and wife can then approach it in a more natural and spontaneous way. The only difficulty is that so many impotent men find it impossible to provide the specimen for insemination. When they can, and when the semen is of good quality, the results are good. If, however, artificial insemination is employed with the object of mitigating the effect of defective spermatogenesis the results are poor. This procedure is also indicated when the woman has some condition of the vagina or cervix which impedes the entrance of spermatozoa into the uterus. It has also been used empirically when no cause for infertility is found in either partner.

The results depend mainly on the indications for which it is employed. In two recent publications successes are reported

TABLE V.—*Seminal Findings Before and After Treatment with Serum Gonadotrophin*

No.	Before Treatment		After Treatment	
	1st Test	2nd Test	Immediately After Treatment	Later
1	2.1 ml. 3 millions; nearly all abnormal		3.6 ml. 22 millions; 50% abnormal	
2	1.8 ml. Too few to count; 0% motile, 100% abnormal		3 ml. 10 millions; occasional ooe motile at 1 hour, 100% abnormal	
3	1.1 ml. 160,000; 0% motile		1 ml. 2 millions; 0% motile at 3 hours, 90% abnormal	
4	5 ml. 50 millions; 100% motile, 10% abnormal	5 ml. 9½ millions; 28% abnormal	After further treatment : 0.8 ml. 39 millions; 36% motile, 65% abnormal	1 child
5	1 ml. 17½ millions; 45% abnormal		4.1 ml. 74 millions; 80% motile, 40% abnormal	
6	1.8 ml. 12½ millions; 1% motile, 80% abnormal		2.75 ml. 19 millions; 80% motile, 50% abnormal	
7	4.2 ml. 5 millions; 10% motile, 95% abnormal		1.8 ml. 25 millions; 14% motile, 50% abnormal	
8	1 ml. 1 million; 100% abnormal	1 ml. 2 millions; 100% abnormal	6.2 ml. 20 millions; 30% motile, 64% abnormal	
9	2 ml. 10 millions; 33% motile, 20% abnormal	3.25 ml. 9 millions; 90% motile, 20% abnormal	1.9 ml. 52 millions; 0% motile, 40% abnormal	0.5 ml. 12 millions; 10% motile, 65% abnormal
10	2 ml. 4 millions; 0% motile, 90% abnormal. (History of G.C. infection)		3 ml. 83 millions; 90% motile, 40% abnormal	3 ml. 26 millions; 60% motile, 60% abnormal
11	2 ml. Azoospermia	1.4 ml. Azoospermia	1.2 ml. Azoospermia	1.8 ml. Only two spermatozoa found in whole specimen
12	3.1 ml. Too few to count; 0% motile, all abnormal		3 ml. 48 millions; 55% motile, 23% abnormal	5.2 ml. 24 millions; 25% motile, 25% abnormal
13	5 ml. 15 millions; 30% motile, 10% abnormal	3.2 ml. Too few to count; 100% abnormal	4 ml. 36 millions; 0% motile, 16% abnormal	
14	2 ml. 20 millions; 20% abnormal		1 child (no further test)	

The numbers of spermatozoa apply to those contained in 1 ml. of fluid.

Motility estimates made at 6 to 8 hours after collection except where otherwise stated.

when azoospermia occurs in association with obstructed tubes the underlying fault is nearly always gonorrhoea in both partners. Four other men who had azoospermia were married to women who had either permanent amenorrhoea and were not ovulating, or menstruated and ovulated very infrequently.

If the husband has only moderate impairment of fertility then the correction of infertility factors in the wife (e.g., replacement of retroversion, dilatation of the cervix, or cauterization of the cervix to make it less hostile, etc.) should be carried out. If the number of normal spermatozoa in the fluid is small and cannot be improved, then it may still be possible to facilitate conception by taking all possible steps to give them every chance of entering the uterus undamaged. In other words, if the fertility of the husband is low it may to some extent be cancelled out by improving the fertility of the wife. In six cases where the husband was considered to be at fault pregnancy followed immediately after dilatation of the cervix or some simple form of treatment applied to the wife, the husband remaining untreated.

Artificial Insemination, Using the Husband's Semen.—The artificial implantation of the semen of the husband into the vagina, cervical canal, or uterus of the woman is by no means a new procedure, and according to Halbrecht (1944) was successfully carried out by John Hunter and Marion Sims. There can be little objection to it save on aesthetic and religious

in two out of 28 cases, and nine out of 30 cases, respectively (Halbrecht, 1944; Barton *et al.*, 1945). This form of treatment was employed in six cases in this series. Two women have had children as a result, and a third had an ectopic pregnancy. In all three cases the inseminations were carried out by the husband—after instruction in the technique. In the case of ectopic pregnancy the insemination cannot be blamed, because the wife had pelvic adhesions with damaged tubes—although this was not realized at the time. The indications in these three cases were a hostile cervix, wide variations in the quality of the semen with possible cervical hostility, and impotence. In the other three cases one woman had damaged tubes (undiagnosed) and suffered an exacerbation of salpingitis after intracervical insemination; one had had the cervix torn off during a difficult labour; while in the third the man had grossly impaired spermatogenesis. However, in none of these three unsuccessful cases were inseminations carried out over a longer period than two menstrual cycles.

Summary of Results.—In addition to four of the 13 men suffering from impotence alone, 26 of the 169 men found to have seminal faults have been responsible for at least one pregnancy since their investigation and the treatment of either themselves or their wives, or both. In nine cases the occurrence of pregnancy immediately after treatment has seemed to indicate a connexion between the two. Any more definite statement seems

unjustifiable, and, bearing in mind how large a part is played by chance in the occurrence of pregnancy, it is perhaps wiser to make no claims for any "cures."

Foetal Abnormalities and Defective Semen.—It has sometimes been urged that male infertility should not be treated, nor should a man with semen of poor quality be encouraged to have a child, because of the possibility of the ovum being fertilized with a faulty spermatozoon, resulting in a malformed child or one deficient in some way. Nevertheless, a relationship between defects in the child and defects in the semen has not yet been established, and Lane-Roberts *et al.* (1939) report negative findings in this respect. In this series only one woman had a malformed child—and that before investigation of infertility—and the seminal fluid of the husband was of reasonably good quality. There are also reports in the literature which indicate that the incidence of abortion is higher when the man's fertility is low. The figures in Table VI are perhaps in keeping with this suggestion, but they certainly do not permit any definite conclusion to be drawn.

Assessment of the Value of Criteria of Male Infertility

In the assessment of male infertility arbitrary standards for the various characters of the semen have to be adopted. It remains to be asked how much value can be placed on these standards when applied to the individual case. Table VI shows

TABLE VI.—Table showing Fertility Before and After Treatment in those Cases Subjected to Semen Analysis

(a) Both had mumps after birth of child—orchitis in one.

(b) Azoospermia to two tests. Further test after pregnancy revealed only two spermatozoa. Pregnancy followed immediately after treatment.

The figures in brackets indicate the number of patients who had had abortions only. These are also included in the figure preceding the brackets.
ect. = ectopic pregnancy.

how many men, classified according to their semen analysis, have proved themselves capable of procreation, either before or after the test. In general the results show that a high proportion of men with a sperm density of over 60 million per ml. are fertile, but it is surprising that 11 men with a sperm count between 21 and 30 millions and eight men with a count between 11 and 20 millions were responsible for pregnancies in their wives. In eight of these 19 cases, however, the pregnancy occurred before the test, and it is possible that spermatogenesis had subsequently deteriorated. Of the 11 whose wives conceived after the test only one had gonadotrophic hormone therapy, and in none was a later rise in sperm count demonstrated. Six men with a count of 3 to 10 millions also had children—four before investigation and two afterwards—again without any proof of improvement in spermatogenesis.

Of 62 men suffering from azoospermia or oligozoospermia to the extent of not more than 2 million per ml., three had impregnated their wives before the time of the test. This again

is perhaps of little significance, since conditions may have changed between the time of the pregnancy and the time of the test; they certainly had in one case, for the husband had had mumps with orchitis. However, four men were responsible for children after the test, and the details are important enough to state.

(1) Azoospermia to two tests. Treatment with gonadotrophin was given, and the wife immediately conceived. The semen was examined again nine months after conception; only two amotile spermatozoa were found in the whole specimen.

(2) Repeated seminal analysis over several years gave such bad results (details unobtainable) that artificial insemination with donated semen had been previously carried out. A child resulted, and eight months later the wife was surprised to find herself pregnant again, the husband undoubtedly being the father. Semen was examined four times soon after the husband had proved his fertility. Azoospermia was found on two occasions, very few spermatozoa on one occasion, and 3 million per ml. at the fourth test. No morphologically abnormal spermatozoa were ever found.

(3) and (4) Both were men with counts of less than 2 million per ml.; neither received treatment, yet both had children.

Another man had azoospermia and testicular atrophy following mumps. He and his wife were both killed during an air raid, but it is stated by friends that she was pregnant at the time. In the absence of further evidence, however, this statement cannot be accepted.

There are several published reports of pregnancy resulting from semen containing only 2 million spermatozoa (see Lane-Roberts *et al.*, 1939; Hamblen, 1945), so in this respect these findings are not remarkable; but pregnancy under such circumstances is not common, and when it does occur it is usually found that of the few spermatozoa present in the semen the majority are well formed. Azoospermia (to two tests) is, however, so often regarded as evidence of absolute sterility that the two cases quoted above deserve emphasis. The most likely explanation is that in these cases the men suffered from some mechanical obstruction in the epididymis or vas rather than defective spermatogenesis, and that the obstruction was not quite complete, so a batch of healthy spermatozoa occasionally leaked through. One man did have a history of mild epididymitis, not of gonococcal origin.

Table VI seems to indicate that so far as sperm density is concerned the standard for reasonable fertility should not be placed too high—and certainly not higher than 30 million per ml. Indeed, unless other unsatisfactory features are present there is much to be said for not diagnosing serious impairment of fertility providing the count is not higher than 10 millions. It should be noted, too, that of 12 cases in which the significant finding was a high percentage of morphological abnormalities, without reduction of the sperm population below 30 million per ml., pregnancy occurred in six. Also, seven out of ten men credited with necrozoospermia or asthenozoospermia were responsible for at least one pregnancy. It would look as though these features alone are not of great significance and that the number of spermatozoa is the best indication of fertility. This statement, however, should be qualified, because pregnancy seems a reasonable possibility if the oligozoospermia is not associated with morphological abnormalities. If a poor semen does not always mean that a man is sterile, then neither does a semen with good characters inevitably mean that he is fertile. This latter is difficult to prove, but the circumstances of some cases provide suggestive evidence—for instance, Seymour (1939) records an extraordinary case in which a man's semen containing 94 million apparently normal spermatozoa per ml. was used to inseminate 16 healthy women and none of them conceived. Yet all the women became pregnant when another donor was used, and so did the wife of the first man. These facts do not mean that male infertility is less prevalent than has previously been stated, but rather that simple seminal analysis as carried out at present is not always an accurate guide. They bring to light the necessity for further inquiry into the characteristics of fluid and cellular constituents of semen and their relationship to fertility. Above all, they serve to emphasize the difficulty in prognosis in any given case. This difficulty is likely to remain even after the most exhaustive seminal studies, and a freak or random pregnancy may result when the chances as assessed scientifically are infinitesimal. Great caution is therefore required in assessing the outlook in

any given case; indeed, it would seem that it is practically impossible to say that a man, or for that matter a woman, is sterile until he or she has died without issue.

For the majority of semen examinations I am indebted to Dr. C. V. Harrison and his staff in the Department of Pathology in the University of Liverpool, who at all times, and often at great inconvenience to themselves, co-operated willingly and gave valuable help.

Summary

From an analysis of 491 private cases and 252 hospital cases it is estimated that not less than one-third of the husbands of infertile marriages have impaired fertility. Of the husbands examined by semen analysis 40% showed evidence of subfertility.

Figures are given to show that responsibility for one pregnancy is unreliable evidence of a man's fertility.

The types of male infertility encountered in 183 cases are set out and some account given of their causes, their treatment, and its results. Of these men thirty have since been responsible for at least one pregnancy.

The results are given of semen analysis before and after treatment with serum gonadotrophin in 14 cases.

The criteria used in the assessment of the findings on simple semen analysis are examined, and attention is drawn to the need for caution in the interpretation of the results and in giving a prognosis in any one case.

TREATMENT OF CARCINOMA OF THE PROSTATE BY PERURETHRAL RESECTION AND STILBOESTROL*

BY

H. T. COX, M.D.Camb., F.R.C.S.Ed.

Surgical Specialist (Temp.), Withington Hospital, Manchester Municipal Service

This paper deals with a personal series of 30 consecutive cases of late carcinoma of the prostate admitted to Withington Hospital during the past four years. These cases share certain points in common. All showed definite extracapsular spread—either locally, in the form of fixation or extension, or generally, as radiological bone secondaries. Perurethral resection was carried out in every case. In those associated with a major degree of urinary retention the routine treatment was early and adequate resection, followed by the administration of stilboestrol. In those with metastatic symptoms, in the absence of urinary symptoms, the resection was limited, and constituted a biopsy only. The diagnosis of malignancy was confirmed beyond doubt by microscopical examination; pathological grading according to Muir's (1934) classification was established in each case. The importance of microscopical examination is well illustrated by one case in which enucleation had been performed for occult carcinoma in 1940, followed two and a half years later by a suprapubic cystostomy for recurrent obstruction. A perurethral resection carried out in an attempt to close the suprapubic cystostomy removed 15 g. of tissue which showed the presence of a squamous carcinoma, arising from squamous metaplasia of glandular epithelium, and thus made clear the cause of stilboestrol failure. This series does not include any case of occult carcinoma—i.e., an early focus of malignancy, first detected by microscopical examination after enucleation.

The initial symptoms in four cases were due to spinal metastases. Three of these patients were bedridden because of pain for periods of three months, two months, and five weeks respectively before admission. In the fourth case the metastases had produced a compression paraplegia up to D 10 of three months' duration. The remaining cases were admitted with acute retention (9), chronic retention type 1 [Cox, 1945] (7), prostatic dysuria (8), and permanent suprapubic cystostomy (2). Three patients in the prostatic dysuria group suffered from sciatic pain. Four cases had previous suprapubic "prostatectomy" performed—two for occult cancer, the symptoms recurring in two and a half and four years, and two for clinically diagnosed cancer, the symptoms recurring in three and eleven months respectively. The data for all the cases are given in the accompanying Table.

Results of Treatment

1. *Perurethral Resection*.—Normal micturition was restored in every case except one—a patient, weighing 22 st. (140 kg.), in whom the external sphincter was unfortunately damaged, producing stress incontinence during the day, nocturnal micturition being normal. No case has yet returned with symptoms of local recurrence, though one returned with a vesical stone and cystitis. This patient failed to attend the follow-up clinic and therefore did not continue with stilboestrol. In this series, which includes five patients over 80, there was one post-operative death, occurring in a patient aged 84. The highest blood urea figures in the chronic retention group were 206 and 103 mg. per 100 ml., occurring in patients aged 83 and 84 respectively. After decompression, controlled by means of intravesical pressure readings, the blood urea figures returned to normal and the patients were successfully resected. Out of the 20 cases in which the urine was personally examined in the follow-up clinic, 3 were definitely infected, 2 had mild infection, and in 15 the urine was crystal-clear.

2. *Stilboestrol*.—The most obvious effect of stilboestrol therapy is unquestionably the dramatic and rapid relief of metastatic or sciatic pain. There has as yet been no failure to produce complete initial relief from this pain. The three patients bedridden with spinal metastases were relieved of pain in four days and out of bed in seven. Initial bone secondaries, where present, have on the whole shown a slow but steady increase in extent. Only one case without initial bone secondaries has so far developed them. The inference from this with regard to early treatment is clear. The majority of cases have shown a varying degree of prostatic softening after some weeks' treatment. The result of stilboestrol in restoring for two and a half years the power of walking to the patient bedridden with compression paraplegia and a complete subarachnoid block is worth a more detailed account. In this patient a left adrenalectomy was carried out in a last attempt to reduce the androgen level.

Case 7.—Aged 45. Admitted to another hospital in August, 1942, with compression paraplegia up to D 10, retention of urine, and incontinence of faeces (preceding nine months' history in which the patient was intermittently off work because of lumbar pain). Notes state: "Left leg, complete flaccid paralysis; right leg, practically complete flaccid paralysis. Sensory loss to pin-prick and cotton-wool up to D 10. Skiagram: Secondary deposits in D 10, ilium, and sacrum. Cerebrospinal fluid: Xanthochromia with massive coagulation; protein, 2.5%; globulin opalescence (Pandy); W.R. negative. Primary lesion was considered to be in the prostate as a result of rectal examination. Patient regained voluntary control of micturition 10 days after admission, on tidal irrigation. Course of deep x rays given, with no improvement." Admitted here November, 1942, with three months' paraplegia. Diagnosis confirmed by resection; case graded Muir Type 2. Stilboestrol 5 mg. daily by intramuscular injection, with 1 mg. three times daily by mouth. Three months later the patient was able to stand by himself. Left epididymo-orchitis developed after resection. Left testis, under combined influence of inflammation and stilboestrol, disappeared. Right testis normal. Improvement continued until the patient could walk two miles with the aid of one stick, and he returned to work. Stilboestrol was continued after discharge in doses of 30 mg. daily (10 mg. thrice daily). Softening of his prostate took place, so that on rectal examination there was no definite evidence of carcinoma. Fit until April, 1945, when he was readmitted with ten days' history of lumbar and sacral pain, increasing in severity until it confined him to bed. Skiagrams showed "secondary deposits in D 5, 10, and 12, and L 1 and 2." Acid serum phosphatase, 2.7 units per 100 ml. Relief of pain by

* A paper read before the Manchester Surgical Society, November, 1945.

changing to dienoestrol 30 mg. daily—i.e., by increasing the dose to the equivalent of 90 mg. of stilboestrol daily. Discharged and returned to work. Readmitted August, 1945, with severe cervical and cranial pain. Skiagram: "Secondary deposits in cervical spine and skull." August 17: acid serum phosphatase, 4.5 units per 100 ml. August 18: orchidectomy. August 28: acid serum phosphatase, 6.4 units. Sept. 6: acid serum phosphatase, 7.5 units. No symptomatic improvement and no reduction in acid serum phosphatase followed orchidectomy, the explanation being provided by microscopical examination of the testis, which showed marked degeneration. Androgen estimation of the urine showed 6.2 mg. 17-ketosteroids in 24 hours. On Sept. 7 I removed the left adrenal in an attempt to obtain a further reduction in androgen. The patient survived the operation for a few hours only.

Many patients while on stilboestrol appear to be unaffected by the existence of spinal metastases. One patient, active for his age (76), has had secondaries in the lumbar spine and pelvis for two years and additional secondaries in the skull for the last nine months. A second patient, admitted bedridden with

Increasing experience with the cold punch and its pin-point coagulation of individual bleeding-points imposes no such handicap.

Three methods exist for the relief of malignant prostatic retention—perurethral resection, suprapubic resection, and suprapubic cystostomy. The object of perurethral resection in this series has been to remove as much malignant tissue as possible down to the prostatic capsule and, where necessary, from all four quadrants. No attempt has been made to "gutter" or "channel" the prostate, except in those cases where the extremely poor condition of the patient has imposed this limited resection or where the operation has been in the nature of a biopsy on a small prostate without urinary symptoms.

The certain and easy identification of the anatomical boundaries—the prostatic capsule and verumontanum—by the perurethral route, and the inability to identify the same structures by the suprapubic route, ensure a larger removal of growth by

Analysis of Cases

Case No.	Age	Initial Acid Serum Phosphatase (K.A. Units)	Perurethral Resection		Path. Grading (Muir Group)	Initial Bone Metastases	Survival Period

28	67	5.2	Aug., 1945	12	2	? In dorsal spine	3 mths.
29	63	58.0	May, 1945	1.2	2	Early in pelvis	4 mths.; died metastases
30	71	9.3	Sept., 1945	6	2	Pelvis and lumbar spine	2 mths.

The acid serum phosphatase estimations in Cases 7 and 17 were made shortly after stilboestrol therapy was started. Case 4 returned one month after discharge with rapidly extending spinal metastases and was first given stilboestrol after readmission. The ages are those at the time of resection. Those patients not written up as dead in the last column are fit for their respective ages.

secondaries in the spine and pelvis, has been back to work for two years. His skiagram now shows further involvement of the spine and secondaries in the skull. He is symptom-free, is active, and has gained in weight.

The following are observations based on the experience of this series.

Perurethral Resection

Two instruments are in common use for perurethral prostatic resection—the McCarthy diathermy loop and the Gershom-Thompson cold punch. The instrument used in this series was the cold punch. The choice of instrument is, I believe, more than one of personal preference. The change over from the diathermy loop to the cold punch followed a skilful demonstration of the latter by Wardill at Newcastle, with a standard of efficiency and a quality of results not attainable with the diathermy loop. The diathermy loop, with its mass coagulation, must leave behind a slough proportionate in size to the amount of tissue removed. Increasing experience with perurethral resection brings with it increasing ability to resect larger prostates and therefore the certainty of leaving behind larger sloughs. This either exposes the patient to the dangers of sepsis or, by excluding these larger prostates, limits the surgeon in his selection of cases. But if the full benefit of the perurethral route is to be obtained large prostates must be fully resected.

the perurethral than by the suprapubic route. If boundaries cannot be identified with certainty surgical excision must stop short to avoid damage to them. Suprapubic resection therefore becomes, in the type of carcinoma under discussion, a disproportionately severe method of removing less tissue, with a diminished chance of restoring normal micturition or an increased likelihood of a return of symptoms. Caulk (1937), in advocating perurethral resection, wrote: "I see little reason for palliative suprapubic cystostomy for the obstruction of cancer of the prostate. I have been shocked to read of its advocacy in many articles and in discussing the subject with many surgeons."

As an alternative method to early and adequate resection in the treatment of urinary retention suprapubic cystostomy followed by stilboestrol has been advocated. Suprapubic cystostomy, however, is associated with a mortality rate estimated at from 15 to 25%. Perurethral resection is in my opinion a more certain, safe, and rapid method of restoring normal micturition.

Pathology

The treated case of carcinoma must constantly be viewed against the background of the untreated case, the life history of which is mainly determined by its degree of pathological malignancy. The pathological grading of the resected material

therefore becomes an essential preliminary step. As sections of carcinoma of the prostate show a well-known variation in appearance in different parts of the same tumour, the tissue examined must be adequate in amount and vary in position. The tissue removed by a full perurethral resection—in this series in amounts up to 31 g.—fulfils both these requirements. Pathological grading according to Muir's classification was carried out in every case.

This classification is into three groups according to the tendency of the growth to form prostatic tubules. In group 1 tubule formation is a prominent feature, mitotic figures being absent. This group represented 25% of 48 cases examined by Muir. In group 3 the bulk of the tumour is undifferentiated, being composed of masses of spheroidal cells with little or no attempt at tubule formation. This group represented 25%. The remaining 50% were placed in group 2, and represented intermediate pathological types. In Muir's series post-mortem examination of 24 patients dying from cancer of the prostate revealed metastases in all of group 3 (6 out of 6), most of group 2 (12 out of 14), and one of group 1 (1 out of 4). Furthermore, the survival periods obtained in group 1 were rather more than double those in group 3. Group 2, while occupying a position intermediate between 1 and 3, shows a closer approximation to group 3 with regard to survival periods and bone metastases.

In support of this established connexion between survival periods and pathological grading, Barnes (1942) considers "it is probable that the survival period in a patient can be more accurately prognosticated from the degree of malignancy discovered than from any other source of information." The data from this short series provide evidence in further support of this view. Of 7 patients placed in group 1, only two had initial bone secondaries. In one of these there was no increase and in the other slight increase in the extent of bone secondaries during treatment. None of the other patients subsequently developed bone secondaries. Two patients have died—one from malignant occlusion of both ureters, surviving a period of two years after resection, the other from hemiplegia three years and two months after resection. The remainder are alive and well.

Case 2, Group 1.—Aged 74. Admitted with retention of urine July and December, 1938. On first admission diagnosed as probable carcinoma on rectal examination. On both these occasions retention relieved by urethral catheterization. Readmitted January, 1942, with a third attack of retention. Blood urea, 86 mg. per 100 ml. Routine decompression and perurethral resection. No stilboestrol given at any time. Micturition completely normal until death from hemiplegia in May, 1945. Acid serum phosphatase, 0.6 unit per 100 ml. No bone secondaries. On rectal examination no change in prostate, which remained large, hard, nodular, and fixed.

As illustrating the correlation between clinical progress and pathological grading, this case is of especial interest. The patient, without any hormone therapy, lived three years and two months after resection for a pathologically proved carcinoma and an additional preceding three and a half years with a clinically diagnosed carcinoma, finally dying of an unassociated disease at the age of 77.

Very dissimilar is the clinical picture of the five cases in group 3. One, originally free from bone secondaries, was readmitted with bone secondaries one month after discharge. These rapidly increased, leading to a fatal termination. The remaining four cases all had initial bone secondaries—massive in two, marked in one, and early in one. This last case developed a fatal increase in secondaries within 12 months:

Case 24.—Prostate hard, irregular, and fixed. Skiagram: "Early secondary deposits in right ischium." Acid serum phosphatase, 2.6 units. Routine decompression and perurethral resection. Stilboestrol 30 mg. daily by mouth. Three months later urine clear, micturition normal, nocturnal frequency 0-1. Small residual mass on rectal examination. Stilboestrol reduced to 5 mg. daily. Five months later patient developed two severe attacks of lumbar pain radiating down both legs. Skiagram: "Further sclerosis in pelvis and spine." Acid serum phosphatase, 30 units. Urine clear, micturition normal. Stilboestrol increased to 30 mg. daily. This reduced acid serum phosphatase to 0.9 unit, with cessation of attacks of pain. Patient did not again attend clinic. Letter from doctor states that he went steadily downhill, became confined to bed because of pain in hip—unrelieved by stilboestrol—weakness, and breathlessness, and died three months after his last attendance.

The advantages of pathological grading are very clear: (1) First and foremost it provides, especially in groups 1 and 3, an approximate survival period for each case. A lack of this

knowledge may render fallacious any attempt to interpret, in terms of survival periods, the benefit of oestrogen therapy or, indeed, any other therapy. The enthusiasm of the stilboestrol era should not be permitted to mask pathological principles. (2) Therapeutic requirements should be affected by a knowledge of the pathological grading. Group 3 cases certainly require maximum treatment. (3) In only one case did bone secondaries develop after resection with such rapidity as to incriminate the operation as a possible cause. Pathological grading showed this case to belong to group 3. The malignant dissemination was therefore attributed to the high degree of malignancy rather than to operative trauma.

Acid Serum Phosphatase

The value of this test is largely dependent on the existence of a well-defined line dividing the normal from the abnormal figures, and the incidence in any series of raised acid serum phosphatase figures depends on the level at which this line is drawn. The upper limit of normal in this country is usually accepted as 2.5 King-Armstrong units per 100 ml. Huggins *et al.* (Huggins and Hodges, 1941; Huggins, Scott, and Hodges, 1941) give the upper limit of normal as approximately 4 units (3.25 ± 1.37), and have found that figures of 10 or over are diagnostic of carcinoma with secondaries. No case of a false positive has been recorded in his series, the word "positive" being taken to refer to a figure of 10 or over. Advanced Paget's disease constitutes the only exception; in this, however, there is an extremely high level of alkaline phosphatase as opposed to the very moderate elevation found in carcinoma of the prostate. A rational estimation based on these figures would classify acid serum phosphatase estimations into three groups—those below 4 units per 100 ml. as normal, those between 4 and 10 as suspicious, and those at or over 10 as diagnostic of carcinoma with secondaries. The data provided in the preceding table show that this series strongly supports this classification. Using the reading of 2.5 units as the upper limit of normal, five patients had acid serum phosphatase estimations above this figure and yet were found to have no initial bone secondaries; nor were secondaries subsequently discovered on repeated examination over an adequate period of time. The practice of recording the acid serum phosphatase estimation to the first decimal place and sometimes even to the second gives to the test a degree of accuracy which in its clinical application it has not been found to possess. This practice may well be discarded.

Of the 12 patients with radiological bone secondaries in whom initial acid serum phosphatase estimations were made, six showed a normal reading (0.8, 1.1, 2.1, 2.0, 2.6, 2.6 units), three a diagnostic rise (4.2, 10.1, and 58 units), and three a suspicious rise (8.8, 5.2, and 9.3 units). False negatives (carcinoma with bone secondaries and a low acid serum phosphatase) are known to occur, but the incidence of them in 50% of cases is sufficient to limit the value of the test and to discredit the value of all normal readings. It is only raised acid serum phosphatase estimations that are of value. One case previously described, with spinal metastases and on stilboestrol 30 mg. daily, developed severe root pains without any increase in the acid serum phosphatase. Another case, also on stilboestrol 30 mg. daily, developed for the first time definite bone secondaries in the lumbar spine and pelvis with no rise in the acid serum phosphatase. These experiences show how fallacious the practice, frequently advocated, may be of relying on the acid serum phosphatase estimation for the control of stilboestrol dosage. With regard to the association between acid serum phosphatase and pathological grading, the three high initial figures were obtained in group 2. It has been suggested that the presence of a raised acid serum phosphatase indicates a serious prognosis. It is rather the failure to reduce such a raised figure, or the progressive and substantial rise of any figure, on an adequate stilboestrol dosage that constitutes a serious prognostic sign. The following case—the only one in which there was failure to reduce a raised acid serum phosphatase—illustrates this point.

Case 29.—Suprapubic resection elsewhere for clinically diagnosed carcinoma of the prostate, 31/1/44. Acid serum phosphatase, 3.2 units. No radiological secondaries. Triphenylchloroethylene given. Readmitted 21/12/44 with dysuria, incontinence, and residual urine 15 oz. (425 ml.). Dienocetol 20 mg. daily for four months with no improvement. 20/2/45: A.S.P. 26 units per 100 ml. Admitted

here 24/5/45: A.S.P., 58 units. Skiagram: "Irregular sclerosis left pelvis; maybe early secondaries. Nil in skull, dorsal or lumbar spine." Inguinal glands enlarged. Perurethral resection, 24/5/45, removing small obstructing nodule near external sphincter, proved on section to be malignant. Residual urine reduced to 1/2 oz. (14 ml.), with complete relief of urinary symptoms. Given 30 mg. dienoestrol daily. A.S.P. (alternate days), 65, 76, 88, 105, 72 units. Home against advice. Returned three weeks later with liver hard and enlarged to umbilicus; inguinal glands larger; A.S.P., 80 units. Bilateral orchidectomy, 8/8/45. A.S.P. still 80 units (28/8/45), with no clinical improvement. Home against advice and died two days later.

Oestrogen Therapy

1. *Dosage*.—"The correct dosage of an endocrine preparation is not a subject for generalization but rather for individualization" (Cameron, 1945). The truth of this statement is shown by at least two case histories. In Case 24 (Muir 3, previously described) the development of sciatic pain, raised acid serum phosphatase, and spinal metastases followed the reduction of stilboestrol from 30 mg. daily to 5 mg. daily. Reverting to the original dose of 30 mg. daily relieved the pain and lowered the acid serum phosphatase to normal. This case also illustrates the disastrous results that may follow continuing treatment on a lowered maintenance dose—a practice often advocated—even when the dose is reduced at a time when the malignant process appears, both clinically and pathologically, to be under control. In the second case severe lumbo-sacral and sciatic pain, intense enough to confine the patient to bed, was completely relieved by changing from stilboestrol 30 mg. daily to dienoestrol 30 mg. daily. (Dienoestrol is stated to be three times as active oestrogenically as stilboestrol.) In the first case 30 mg. of stilboestrol daily proved to be an adequate dose; in the second case it was inadequate.

These cases demonstrate clearly that an apparent stilboestrol failure may be due to an actual error in dosage. The impression gained from the literature, especially American, is that the dosage of stilboestrol administered has been too low. One author states that he found castration alone more effective than oestrogen alone. The explanation of this anomaly he himself provides by stating that the dose of stilboestrol given was "one or more milligrams daily." I believe the dose of stilboestrol should be large, that it should never be lowered in group 3 cases, that it is wiser not to lower it in group 2, and that it is safe, subject to the results of repeated examinations, to lower it in group 1. My practice in the later cases of this series has been to begin treatment on 30 mg. stilboestrol daily.

2. *Cardiac Complications*.—Four patients have developed cardiac complications while on stilboestrol. This has been accepted as a disquieting incidence, although in this advanced age group the association of degenerative changes with any form of treatment may be more apparent than real. In three cases acute congestive heart failure developed—in the first after three weeks on stilboestrol 20 mg. daily by mouth, in the second after six weeks on stilboestrol 5 mg. daily by intramuscular injection, in the third after two years on 15 mg. daily for the first year and 10 mg. daily for the second. Two cases had extensive spinal metastases, and in one of these definite evidence of myocardial degeneration was present before stilboestrol was started. The third case, a patient weighing 22 st. (140 kg.), also had signs of initial myocardial degeneration. The connexion between stilboestrol therapy and cardiac complications was, at any rate, beyond dispute in the fourth case. This patient, an intelligent man under close observation in the follow-up clinic, while on stilboestrol 10 mg. daily developed pain across the front of the lower chest on exertion, increasing in intensity until, after a period of three months, it was induced in a severe form by such mild exertion as getting out of bed. Changing from stilboestrol to dienoestrol relieved this pain. The development of nausea in four cases necessitated a change from stilboestrol. Dienoestrol was substituted in each instance with complete relief. In view of these experiences it is proposed to treat all future cases with dienoestrol in preference to stilboestrol.

3. *Relation to Prostatic Obstruction*.—The early relief of a major degree of prostatic obstruction by stilboestrol in adequate doses has proved a complete failure in the two cases in which it was attempted. Furthermore, a third patient, while in hospital on stilboestrol 20 mg. daily, developed an acute retention with a bladder distension to 1 in. (2.5 cm.) from the umbilicus

eleven days after the beginning of treatment. The stilboestrol had in the meantime completely relieved his pain from spinal metastases. Three cases—two with acute retention and one with prostatic dysuria, all subsequently proved to be group 1—were relieved of symptoms by catheterization without stilboestrol for periods of one month, four years, and twelve months respectively. These latter experiences demonstrate clearly that the factors responsible for urinary retention or dysuria may be of a temporary nature even in malignant prostates and that early or immediate relief of such symptoms, if occurring while the patient is on stilboestrol, may be erroneously attributed to it. Reports of immediate or early relief of retention by stilboestrol should be viewed with considerable scepticism.

Orchidectomy.—The two cases in which orchidectomy was carried out after stilboestrol or dienoestrol, in adequate doses, failed to show any improvement either clinically or in reduction of acid serum phosphatase.

Summary

Suprapubic cystostomy and suprapubic resection as methods of relieving malignant prostatic retention are unjustifiable survivals of pre-endoscopic days. Normal micturition can and should be restored by perurethral resection.

The importance of pathological grading in assessing survival periods and of giving and continuing to give oestrogen in adequate doses has been stressed.

Reasons for a proposed change from stilboestrol to dienoestrol have been given.

Observations on the acid serum phosphatase in the blood have been made.

I should like to thank Dr. J. M. Greenwood, medical superintendent, for facilities for treating these patients.

THE OUTBREAK OF SMALLPOX IN MIDDLESEX, 1944

BY

W. H. BRADLEY, D.M.Oxon
Medical Officer, Ministry of Health

J. O. F. DAVIES, M.D., D.P.H.
Principal Assistant Medical Officer, Middlesex County Council

AND

JAMES A. DURANTE, M.R.C.S.
Formerly Temporary Medical Officer, Ministry of Health

A case of variola major in a large hospital in Middlesex in 1944 was followed by 10 further cases, three of them fatal. The outbreak is thought to be of interest in that the diagnosis was not made in the primary case until the patient was ambulant in hospital, by which time six other persons had been infected—three nurses and a patient in the hospital, a nurse on leave at home, and a visitor. The diagnosis of smallpox in the nurse on leave drew attention to the outbreak. After the isolation of these secondary cases four others occurred.

Case Histories

Case 1.—L. C., a soldier aged 23, had arrived in convoy from Gibraltar on Feb. 6, and had been admitted direct to the hospital on account of an anxiety state. He had slight fever on admission, which became more pronounced on succeeding days. On Feb. 10 an erythematous rash appeared and his temperature rose to 103° F. (39.4° C.). A rubella-like eruption the next day was followed two days later by lesions suggesting chickenpox, so that on Feb. 13 the diagnosis of chickenpox with rubella was made and the patient barrier-nursed in a four-bedded ward until Feb. 24. Later the patient was up and about, and subsequently visited other parts of the hospital. A barber visiting the hospital cut his hair in company with that of a number of other patients.

When seen on March 2, the soldier had a few faint scars on the forehead, a number of seeds in the soles of the feet, one seed under a finger-nail, and a few scabs on the dorsa of the feet. He bore good vaccination marks from infancy, and a single scar from revaccination dated in his Army pay-book Sept. 17, 1942. Nevertheless, the condition from which he had been suffering appeared without doubt to be smallpox.

Case 2.—Nurse E. H., aged 24, unvaccinated, at home in Finchley on leave, became unwell on Feb. 22 with a bilious attack and vomiting. On Feb. 24 she developed a morbilliform rash, and on Feb. 28 vesicular lesions appeared on the hands and fingers. The following day the rash was profuse, and smallpox was suspected by the medical officer of health. This diagnosis was confirmed next day, when the patient showed a confluent early pustular rash on the face, upper chest, and back, with discrete but copious late vesicular lesions on the feet and legs. Many of the papules were haemorrhagic, and the vesicles showed central bluish haemorrhage. Death occurred on March 3.

A history of contact with a case diagnosed as rubella and chickenpox led to a visit to the hospital, with the discovery there of Case 1 and the four cases next described.

Case 3.—Nurse N. P., aged 22, who had nursed Case 1 at night, fell ill on Feb. 22 and reported sick on the 25th. She was admitted to the hospital sick bay that day, and transferred later the same day to a cubicle in the isolation ward as a chickenpox suspect. On March 2 a discrete modified pustular rash of scanty but typical

died on March 2. When first seen this patient had a temperature of 103° F. (39.4° C.), and was thought to have measles. Two days later there was a profuse papular eruption of general distribution, but most marked in the flexures, on a dusky red background. There were petechial haemorrhages, giving an appearance of erythema multiforme plus purpura. Oedema of the face and eyelids was marked, as were conjunctival haemorrhages. She died with her case undiagnosed, but it was undoubtedly haemorrhagic smallpox. This completed the secondary cases.

Cases 8 and 9.—On March 9 and 10 F. H. and I. H., two sisters of Case 2, one of whom had nursed her at home for eight days, fell ill and developed a rash, diagnosed as smallpox, on March 12 and 13 respectively. They had been successfully vaccinated on March 2. The eruption in the sister who had acted as nurse was profuse; the other was less so, and she was reported to have had no actual physical contact with Case 2. Both girls recovered.

Case 10.—M. H., an unvaccinated youth aged 17, who had been admitted from another hospital on Feb. 18, was transferred to a cubicle in the isolation ward on Feb. 24 with chickenpox. His cubicle was in the same corridor as that to which Cases 3 and 4 had been moved, all three patients being nursed by the same staff. There was no evidence of any direct contact with the nurse-patients (Cases 3 and 4). When seen on March 2 he had a very profuse chickenpox rash with an abnormally high incidence of lesions on the face and forearms. Despite this, no doubt was entertained that the condition was chickenpox. He was primarily vaccinated that evening, and vaccination developed typically into a large pustule

Table of Principal Clinical Features and Relevant Dates

Case	Age	Successful Vaccination	Source of Infection	Probable Date of Infection	Date of Onset of Symptoms	Date of Efflorescence of Rash	Type	First Day of Exposure to Infection	Remarks
L. C. 1	23	Infancy and 17/9/42	Mediterranean port	27/1/44	7/2/44	10/2/44	Discrete, modified	?	? Prodromal erythema, "chickenpox" lesions on 12/2/44. Primary case
E. H. 2	24	None	L. C.	10/2/44	22/2/44	24/2/44	Confluent, haemorrhagic	7/2/44	Died on 3/3/44
N. P. 3	22	Infancy	L. C.	13/2/44	25/2/44	26/2/44	Discrete, modified	7/2/44	? Prodromal erythema. Chickenpox spots noticed on 28/2/44
M. G. 4	20	Infancy	L. C.	13/2/44	25/2/44	28/2/44	Discrete, modified	7/2/44	
N. B. 5	34	Infancy	L. C.	14/2/44	26/2/44	28/2/44	Discrete, modified; scanty rash	7/2/44	First seen with vesicular rash 3/3/44
M. L. 6	51	Infancy	L. C.; fomites	17/2/44	29/2/44	2/3/44	Confluent, haemorrhagic	7/2/44	Died on 5/3/44
M. C. 7	36	None	L. C.	10/2/44	22/2/44	27/2/44	? Purpura haemorrhagica variolosa	5/2/44	Died, undiagnosed, on March 2, 1944. Labelled erythema multiforme
F. H. 8	32	Primary 2/3/44	E. H.	27/2/44	9/3/44	11/3/44	Discrete, modified	22/2/44	Sister to E. H.; vaccinated successfully 9 days after exposure
I. H. 9	19	Primary 2/3/44	E. H.	28/2/44	10/3/44	12/3/44	Discrete, v. modified; scanty rash	22/2/44	Sister to E. H.; vaccinated successfully 9 days after exposure
M. H. 10	17	Primary 2/3/44	N. P. or M. G.	28/2/44	10/3/44	13/3/44	Discrete, profuse	25/2/44	Suffering from varicella. Contracted variola subsequently
F. T. 11	56	Infancy and 6/3/44	N. B.	3/3/44	? 13/3/44	15/3/44	Discrete, profuse, modified	3/3/44	Ambulance driver; took N. B. to smallpox hospital. Successfully vaccinated 1914-18 war. "Failed to take" three times prior to March 6.

The numbers refer to the preceding clinical notes.

smallpox distribution was present. She had been vaccinated at the age of 3 or 4 years.

Case 4.—Another contact, Nurse M. G., aged 20, vaccinated successfully in infancy, reported sick on the 25th, having been first unwell on Feb. 22. She was admitted to a cubicle in the isolation ward, where chickenpox was diagnosed on the 27th. On March 2 his nurse showed a moderately profuse papular rash of typical malpox distribution, which (seen later) evolved rapidly with much modification of individual lesions.

Case 5.—Nurse N. B., aged 34, vaccinated successfully in infancy, and also nursed Case 1. This nurse lived at home. She felt unwell on Feb. 26 and went to bed at home, where a diagnosis of chickenpox was revised to smallpox on March 3. When seen later many of the lesions were aborting in all stages of evolution.

Case 6.—This patient, aged 51, suffered from carcinoma of the breast in a ward on the same corridor as Case 1, but separated from him by an intervening ward. The nursing staff, however, were common to the two wards. On Feb. 29 this patient had a temperature of 101° F. (38.3° C.), which rose to 105° F. (40.6° C.) on March 2. Seen the next day, she presented a very profuse bluish purple papular rash of typical smallpox distribution. On the face the lesions were so close as to appear as a uniform coloration of the skin. They were suggestive of a toxic haemorrhagic attack, and this proved to be the case, the patient dying on March 6 with a confluent haemorrhagic eruption little beyond the papular stage. Haematuria, melacna, and metrorrhagia preceded death. The marks of vaccination in infancy were present.

Case 7.—On March 3 it was learned that an unvaccinated woman (M. C.), who on Feb. 12 had visited another officer in the same ward as Case 1, had been taken ill in Bedford on Feb. 22, took to her bed on the 24th, two days before a rash appeared on Feb. 26, and

with extensive erythema and some adenitis. On the 10th the boy developed slight fever which rose to 105° F. (40.6° C.) on March 12. On the 13th there was a discrete profuse macular rash, contrasting vividly with the scars of the almost faded chickenpox rash. He developed modified smallpox.

Case 11.—The only other case to occur was that of an ambulance driver (F. T.) who removed Case 5 in the early hours of March 3. He was not revaccinated until March 6, and developed a rash on March 15. He had been successfully vaccinated in infancy and during the 1914-18 war. Vaccination was stated to have failed to take three times before March 6.

These cases are set out in the accompanying Table.

Transmission of Infection

Cases 2, 3, 4, 5, and 7 were all direct contacts of Case 1. Case 6 never made actual contact with Case 1, but was attended by the same nurses. Cases 8 and 9 were direct contacts of Case 2. Case 10 was infected from Cases 3 and 4, but without obvious contact. Case 11 was a direct contact of Case 5.

Action taken at the Hospital

The hospital was closed to further admissions; discharges were discontinued, and control measures—vaccination and surveillance of all close contacts—immediately applied. Since the infection had been present in the hospital for a relatively long period before detection, the number of possible contacts, both inside and outside the hospital, was large, and their identification a formidable task. Yet, so long as no unexplained case arose, it was felt that vaccination might be confined to persons

working at the hospital, possible contacts in the neighbourhood, and such visitors as investigation might show to have been possible contacts. Mass vaccination was not advised, but to allay local anxiety and to assist the Public Vaccinator, the medical officer of health of the local authority opened a vaccination clinic, at which those resident in the vicinity of the hospital could be vaccinated if they so wished.

By the evening of March 4 all patients and all members of the staff working at the hospital (approximately 1,100 persons) had been vaccinated, about 120 of them for the first time. On the same evening all members of the nursing, domestic, and laundry staff, etc., were inspected for rash on the head, neck, and arms, and all interrogated as to possible contact with any of the known sufferers. One or two girls who were not feeling well were kept under close observation, and the necessity for reporting sick at once if unwell was made clear to all.

The hospital consists of a main block (the original building) and a number of hutted wards erected as a wartime measure. The cases had occurred in the main block and in the isolation hut. These two buildings were placed out of bounds to all save the staff who worked there. Members of the staff were requested for the time being to limit their contacts and refrain from entering crowded places. For the observation of persons reporting sick arrangements were made to set aside one block containing a number of cubicles and two small wards. This proved extremely valuable for the observation of the numerous vaccinia rashes and reactions which appeared. All members of the staff, resident and non-resident, were kept under daily observation, and any non-resident members not attending for duty were reported to the medical officer of health of their place of residence. The laundry was dealt with in part at the hospital and in part at a public laundry in a near-by town. No infected laundry had gone outside, and arrangements were made that none should go.

Among the nurses who had been previously unvaccinated seven had had close contact with cases of smallpox. These were housed in a separate building in the grounds from March 8 to 16, and did not report for duty. Had smallpox developed in any of these nurses the contact would have been strictly limited to the medical officers observing them and one sister-in-charge. Although one nurse on the twelfth day after contact aroused some anxiety by reason of fever, headache, and backache, she did not develop smallpox.

Case 10 occurred in the isolation ward amongst a well-vaccinated community, and was removed to the smallpox hospital on March 13. From that date this ward was separated by physical barriers from the rest of the hospital. Arrangements were made for the nurses working in the isolation ward to sleep and feed in a nurses' hut next to that ward. No further cases developed from Case 10.

It became clear that the number of persons who might have been contacts was very considerable, and it was decided to notify medical officers of health of all patients discharged from the hospital between Feb. 6 and March 1 and of all visitors during that period. The patients were asked to prepare a list of their visitors between the dates mentioned. Names of visitors known to have entered smallpox wards were notified direct to the medical officer of health of their place of residence; all other visitors received a letter from patients, so worded that when the visitor took the letter as instructed to the medical officer of health it would be clear to the latter that this person was not thought to be in any appreciable danger. In this way it was hoped that the very large number who might possibly have been at risk would be brought under surveillance.

The hospital was freed from quarantine on March 17, with the exception of the main block, the isolation ward, and the ward used for observation cases. On March 20 the main block was freed for the admission of patients after cleansing had been carried out, and the other wards a week later.

Comment

The strain of variola major in this outbreak was of a high degree of virulence. Both the unvaccinated patients died from confluent haemorrhagic smallpox. Also, a modified attack occurred in Case 1; this patient, having been successfully vaccinated in infancy and 18 months previously, might have been expected to escape.

In spite of its virulence the disease was greatly modified by vaccination. The three nurses vaccinated in infancy—approximately 20 years previously—had mild modified attacks. Case 11, vaccinated in infancy and subsequently, was vaccinated four days after exposure and developed a profuse discrete but modified smallpox nine days later. Three previously unvaccinated persons (Cases 8, 9, and 10), vaccinated too late in the incubation period to afford complete protection, sustained modified attacks. The interval between vaccination and the appearance of the rash in those previously unvaccinated was 9, 10, and 11 days, suggesting that vaccination may have been performed on the fifth, fourth, and third days after the infection was contracted.

Wanklyn states that good marks of recent vaccination can be taken as evidence that an eruption is not smallpox. It would appear from Case 1 that this does not hold in the presence of a virulent strain. Nevertheless, the value of successful vaccination in mitigating the severity of an attack of smallpox even when, owing to lapse of time, it may not confer absolute protection, appears to be demonstrated by Cases 3, 4, and 5, whose vaccination dated back to infancy, some 20 years previously. The pronounced modification in Cases 8 and 9, whose sister died from a confluent haemorrhagic attack, appears to have been achieved by vaccination performed five and four days respectively after the infection had been contracted.

Case 1 was so much modified as to deceive competent medical opinion. In nearly all the vaccinated persons the lesions varied greatly in size, a large proportion aborting in the papular or vesicular stage. These lesions, together with the tendency for the rash to run a more rapid course, produced a picture simulating chickenpox, which, associated with the concurrent prevalence of the latter disease in the hospital, added to the difficulties of diagnosis.

After the isolation of the primary case and those infected by that patient, and the complete vaccination of the hospital population and outside contacts, there was no extension of the outbreak in the hospital apart from Case 10. The cases which did occur after the institution of these measures—Nos. 8, 9, and 11—acquired their infection outside the hospital.

Considering the opportunities for spreading the disease afforded by the primary case, by the number of unvaccinated persons in the hospital population, and by the virulence of the virus, the persons infected were remarkably few.

Conclusion

The experience of this outbreak suggests that control was achieved by the careful ascertainment, vaccination, and surveillance of contacts without embarking on the vaccination of the population generally. Of the seven nurses kept under close supervision because they were unvaccinated at the time of intimate exposure to infection, none developed smallpox. Nevertheless, one, as has been described, did develop headache, fever, and backache, and in four well-vaccinated nurses who had handled smallpox patients unexplained pyrexia without rash occurred under circumstances suggesting that they were reacting to the variola virus (Downie, 1946). There was serological evidence for this statement, and undoubtedly the virus was available in the hospital for the infection of nurses and patients. The failure of the disease to spread is attributed to vaccination.

At the present time importation of smallpox by returning Service men is a frequent occurrence. In these men the disease is modified, and may be misdiagnosed. It would therefore seem to be a wise precaution to employ only well-vaccinated persons in general hospitals, as well as in infectious disease hospitals.

With a view to securing a more constructive type of legislation the National Smoke Abatement Society (Chandos House, Buckingham Gate, London, S.W.1) is putting forward for discussion preliminary proposals for extensions of the Public Health Acts by means of which local authorities could obtain bylaws that will help to prevent smoke and will directly encourage fuel efficiency and coal conservation. Three sets of bylaws are proposed. Details may be had from the society.

A CASE OF MERCURIAL POISONING AND ITS TREATMENT

BY

R. HAYDEN ELLIS, M.B., B.Chir.

A case of acute mercurial poisoning is described below in which there were severe gastro-intestinal symptoms and anuria lasting 5 days. The 5 ml. of urine passed the preceding day contained red and white blood cells and many hyaline casts—albuminuria was slight; oedema was absent. Recovery set in after suddenly on the eighth day, when the kidneys began to secrete a pale, low-specific-gravity urine containing microscopical blood, excess of leucocytes, and numerous hyaline and granular casts. The urine was normal by the twenty-fourth day. Apart from symptomatic remedies the basis of treatment was intravenous therapy. In all, 32 pints (18 litres) of fluid were given intravenously.

Report of Case

The patient, a young man of 20, was admitted in March, 1946, with severe abdominal pain, vomiting, and diarrhoea. Sixteen hours before admission he had taken 3 g. of corrosive sublimate in a glass of water. Half an hour later he vomited blood, and suffered severe abdominal pain with the passage of fresh blood per rectum. Three hours later there was frank haematuria. He was seen by a doctor, and given the whites of three eggs in a glass of milk and an injection of morphine, 1/4 gr. (16 mg.). The morphine was repeated in three hours because of great pain and restlessness, and he was then removed to hospital by ambulance. Blood-stained urine was passed during transit, but the specimen was not saved.

On examination the patient looked very ill and was obviously in great pain. There were bouts of colic, followed by the passage of blood-clots and mucus per rectum, about every half-hour. Vomiting was frequent, and the vomit consisted of bile and blood-clots. The mental condition was clear. Abdominal movement was restricted; there was diffuse tenderness, and gentle palpation was followed by violent bowel action and much pain. There was also some tenderness in the loins. His blood pressure was 152/74.

Progress and Treatment

On the second day pain, diarrhoea, and vomiting continued; stools were passed at the rate of one an hour and were darker in colour. During the day the patient passed 5 ml. of urine containing a small quantity of albumin. The centrifuged deposit showed occasional red blood cells, white cells, and many hyaline casts. Kaolin poultices were placed over the loins. Water and sips of iced orangeade were taken. Restlessness and pain were treated with morphine, 1/4 gr. four-hourly. Frequent vomiting continued, and much fluid was lost in the faeces. An intravenous drip was started in the left arm, and fluid was given at the rate of 4 pints (2.27 litres) in 24 hours—namely, alternating pints of dextrose-saline (4.8% and N/5), sodium sulphate (4.2%), and normal saline.

By the third morning the patient was very drowsy and there was twitching in the limbs. The tongue was covered with brown fur, and he complained of severe headache. Morphine, 1/4 gr. four-hourly, and the intravenous drip were continued. He vomited 1 litre during the day, but passed no urine. There was little improvement over the next three days, though the abdominal pain was less and the stools not so frequent. No urine had been passed since the original 5 ml. after admission. The patient was now mentally alert, and worried about himself. Blood urea was 236 mg. per 100 ml., and the patient was very ill. All veins except one had now been utilized, and the intravenous administration of fluid was discontinued. On the seventh day the abdominal tenderness had disappeared, the diarrhoea and vomiting had improved slightly, but the patient was hiccuping continuously. The plantar responses were extensor. Blood pressure, 174/84; blood urea, 350 mg./100 ml. Morphine was changed to heroin, 1/8 gr. (8 mg.) four-hourly, as this was thought less likely to aggravate vomiting.

On the morning of the eighth day the patient's condition was critical. No urine had been passed since the second day (5 ml.). Intravenous therapy had been stopped for 24 hours on account of technical difficulties, and was begun again—namely, dextrose-saline at the rate of 4 pints (2.27 litres) in 24 hours. During the day and following night 1.85 litres of urine was passed, and the patient's condition improved. The next day there was a pronounced improvement: 1.9 litres of urine, of specific gravity 1010, was passed; twitching and headache abated; and the patient was able to take rusks and 1.7 litres of fluid by mouth. Blood urea, 300 mg./100 ml.; haemoglobin, 65%; W.B.C., 21,000.

Over the course of the next three days intravenous dextrose-saline was continued and the diuresis and general improvement were maintained. Vomiting was less, and the patient was able to take solid

food in the form of eggs and custard, calves'-foot jelly, rusks, and pounded fish. At the end of this time the last vein had thrombosed, and the drip was discontinued. Blood urea, 380 mg./100 ml.; plasma chlorides, 419 mg. NaCl/100 ml.; alkali reserve, 42 vols. CO₂%; blood pressure, 150/60. The heroin had been discontinued, and phenobarbitone, 1/2 gr. (32 mg.) four-hourly, was given in its place. In spite of the high blood-urea figure the patient felt well and was cheerful.

On the 17th day after admission the blood urea was 170 mg./100 ml.; plasma chlorides, 487 mg. NaCl/100 ml.; alkali reserve, 52 vols. CO₂%. The centrifuged deposit of each specimen of urine passed showed successively diminishing numbers of red and white blood cells, and all showed persisting hyaline and granular casts. On the 24th day the patient was his normal self, eating well, with no vomiting, and passing one semi-solid darkish stool per day. The urinary output was in the region of 2 litres in 24 hours; the blood urea was down to 63 mg./100 ml.; plasma chlorides had been raised to the normal level of 576 mg. NaCl/100 ml., helped by the giving of 5 g. of NaCl daily in a litre of lime-juice; alkali reserve, 56.7 vols. CO₂%; blood pressure, 148/63. The urine contained no albumin and the centrifuged deposit was normal.

THE SYNDROME KNOWN AS "REITER'S DISEASE"

(A TRIAD OF POLYARTHRITIS, URETHRITIS, AND CONJUNCTIVITIS)

BY

W. P. U. JACKSON, M.B., M.R.C.P.

Fl.-Lieut., R.A.F.V.R.; formerly Medical Specialist in the Bahamas

In 1916 Reiter, in Germany, reported the case of a young man in whom the presenting clinical features were the triad of polyarthritis, urethritis, and conjunctivitis. Fever and, at the onset, bloody diarrhoea were also present. The patient made a complete recovery. No previously recognized pathogen was discovered to account for these inflammatory reactions, but Reiter believed he had incriminated a spirochaete, for which, however, there has been no subsequent evidence. This syndrome of the "inflammatory triad" does apparently represent a disease *sui generis*, its aetiology being unknown. Kuske (1939) noted cutaneous eruptions to be frequent concomitants, and others have found a haematuria. Recently Miller and McIntyre (1945), in America, reviewed the condition and found that about 65 cases had been reported, mostly in Germany, some in America (e.g., Bauer and Engleman (1942), 6 cases). In a lecture in this country on keratoderma blennorrhagica, Harkness (1945) remarks in passing upon several cases of Reiter's disease seen by him, and notes that 16 cases have been reported in the literature in combination with this particular skin lesion. Apart from this brief mention I have not found a report on the syndrome in British journals.

Clinical Manifestations

The patient is usually a young adult male, presenting with an irregular fever and any one or more of the triad of essential symptoms. If one (e.g., the arthritis) occurs alone at first, the others (i.e., urethritis and conjunctivitis) develop later. The *conjunctivitis* is bilateral, catarrhal, or, more usually, profusely purulent, with episcleritis and sometimes an iritis or keratitis. There are local pain, weeping, and photophobia, but permanent damage to the eye does not occur. No constant organism can be found in conjunctival smears. The *arthritis* is manifested by severe pain and tenderness, occurs in the large joints of the limbs, is usually polyarthritic and often flitting. Synovitis is frequent, fluid developing rapidly and in considerable amount. This fluid may be purulent, but is always sterile. The *urethral discharge* is abundant and purulent, accompanied by surprisingly little frequency of, or pain on, micturition. Gross haematuria may occur (as in the two cases of Miller and McIntyre) and renal complications have been described. The urine contains red blood cells in varying numbers, clumps of pus cells, and a little albumin. The discharge presents no evident organism and is sterile on attempted culture. Erosions and small ulcers may appear on the penis from the constant irritating discharge.

Diarrhoea, sometimes severe and bloody, may be present at the onset, and several types of more or less generalized rashes have been described. The erythrocyte sedimentation rate is

raised, there may be a mild hypochromic anaemia, and the leucocytes are normal or slightly raised in number. Gonococcal fixation and Wassermann tests are negative. The disease is self-limited, though subject to recurrences, which may drag its course out into months. Complications are very rare.

Aetiology and Differential Diagnosis

Harkness claims to have demonstrated inclusion bodies in the discharge from the urethra and conjunctiva in five cases of Reiter's disease. Apart from this all efforts to discover an infecting agent have failed, although the hypothesis of virus causation is the most popular. Reiter's spirillum has not been seen since 1916. One thing seems certain—this is no venereal disease, and bears no relation to gonorrhoea or syphilis. There is no reason to believe that it is caused by gonococci "lurking in the background," as has been mooted.

The inflammatory triad of symptoms may occur in gonococcal infection, but here there will be a history of venal contact, and of urethritis well preceding the other symptoms. Pus from all sources will contain gonococci (except that the conjunctivitis may be catarrhal, metastatic, and non-infective), the fixation test will usually be positive, the course and response to treatment different. Secondary syphilis might be confused on account of the fever, rash, and keratoconjunctivitis. Penile erosions also occur in both diseases, but differ in their appearance, time relation to other symptoms, and bacteriology. Syphilis could not account for the urethritis. Rheumatic fever may be simulated if flitting polyarthritis is the presenting symptom, together with fever and night sweats. Reiter's disease does not respond to salicylates.

Treatment

Miller and McIntyre consider that putting the patient to bed for six weeks to three months is all that can be done. They found penicillin and sulphonamides to have no effect on their two cases. Protein shock therapy has been used in Germany, apparently with some success, especially by Beiglboeck (1943). Sulphadiazine, however, seemed to have a good effect in the cases noted below.

Case Reports

Two patients with Reiter's disease were seen in the Bahamas last year—one a British airman and the other a coloured Bahaman. Though they presented within a fortnight of each other there was no history of close contact between them to render likely the transfer of infection. Their stories were briefly as follows.

Case I

A Scottish leading aircraftman aged 30, employed as a batman for 4½ years, complained on April 5, 1945, of pain in and limping on the left foot. This had been coming on in the mornings for about three weeks, and had got worse. The previous January he had been in the R.A.F. hospital with a painful swollen left knee, which settled down completely after it had been opened and the pus had been evacuated. This pus was apparently sterile. The patient (who was a very reliable and honest person) denied intercourse since leaving England. There was no history of trauma.

On examination the patient was rather flushed and feverish. His skin was bathed in sweat and his temperature was 101° F. (38.3° C.). The body of the left foot was red, hot, and swollen, with thickening and some oedema of the tarsal periarticular tissues. The ankle was less affected, but showed some painful limitation of flexion and extension. There was also a moderate bilateral catarrhal conjunctivitis with episcleritis, of three days' duration according to the patient. There were no other noteworthy signs in any system. By next morning the right knee had become very swollen, warm, and tender, and there was a large synovial effusion. A little serous, slightly purulent fluid was aspirated for examination. No organisms were found in it, and it remained sterile on attempted culture. A full blood count was normal, white blood cells numbering 6,000, with 60% polymorphs. On the 14th the conjunctivitis, which had subsided fairly rapidly, flared up again, this time with rather more mucopurulent discharge. This subsided within a week. On the 18th a yellowish profuse purulent urethral discharge started, and within twenty-four hours two small erosions had appeared on the glans penis. No organisms could be found in the discharge, and rectal examination showed nothing abnormal. The two-glass urine test, with threads and debris in the first glass, suggested an anterior urethritis. No facilities were available for performing the gonococcal fixation test, but the Kahn test was negative. There had been little or no change in the affected joints, and there were fleeting pains in other joints, including those of the upper limbs.

On the 20th a course of sulphathiazole was started—8 g. the first day and 6 g. on succeeding days. The drug was stopped after total of 32 g. had been given. The fever, which had remained low and intermittent, with peaks of 100–101° F. (37.8–38.3° C.), since admission, stopped on the fourth day of the course, and stayed down. The urethral discharge also subsided and did not recur. Flitting joint pains remained. Tender purple raised irregular areas appeared on the palm of the right hand but disappeared within a few days.

By May 23 a gradual subsidence of joint pains and swelling had occurred. The most bothersome joint was now the right ankle which remained somewhat swollen and painful, causing a limp. The patient was discharged on June 6. The ankle continued to give him a little trouble for some weeks, but gradually got better.

Case II

On April 19, 1945, a coloured Bahaman aircraftman aged 27 complained of a pain in the left chest and left shoulder while carrying his meal to his table at lunch-time. After this he felt sleepy and unwell, and experienced some pain on inspiration. There were no other complaints. He denied sexual intercourse since January. The previous year he had been in the civilian hospital with a urethral discharge, but its nature was not known.

On examination he was found to have a temperature of 102° F. (38.9° C.), with a pulse of 106. His left lower intercostals were tender to digital pressure. He had a profuse purulent urethral discharge, but was vague as to its duration, though quite definite that it was very recent. Further examination, including a rectal one, revealed nothing significant. A blood count and a skiagram of the chest were both normal. The discharge showed pus and epithelial cells, but repeated examination failed to reveal gonococci. By the 23rd the pains in the chest had gone, but the patient was experiencing fairly severe flitting polyarthralgia. The affected joints would become painful, tender to touch, and warm, with restricted movement, but there was no inflammatory localization. He was given a course of sulphathiazole—26 g. in four days.

On the 25th a bilateral catarrhal conjunctivitis started. This was never severe and cleared up within a few days. By the 28th the urethral discharge was over, and the low irregular fever, present since admission, had stopped. He was discharged on May 1, and had not heard of any recurrence.

It is realized that this case is not so definite as the first. It might be objected that the conjunctivitis was a manifestation of sulphathiazole sensitivity, but this is unlikely to occur before the fifth day (M.R.C. War Memo. No. 10, 1945). Chronic gonorrhoea is improbable without evidence of genito-urinary involvement deeper than the urethra, and would not be expected to clear so rapidly simply on chemotherapy, especially as the patient's urethritis had been treated with sulphonamides the previous year. Considered together, the febrile polyarthralgia, purulent bacterial urethritis, and conjunctivitis make Reiter's disease a highly probable diagnosis.

There was another coloured Service man the diagnosis of whose illness had been in doubt, but who, in retrospect, showed some features suggestive of Reiter's disease, though without urethritis having been discovered.

Case III

A lance-corporal cook aged 29 was admitted to hospital on March 21, 1945, for pain in the left lower limb. A year earlier he had fallen and twisted the left ankle and foot, since when he had had intermittent aching in the region of the first-metatarsophalangeal joint, spreading up the leg as far as, and into, the knee. More recently he had been almost unable to walk, and had been on duty for 18 days. There were no other complaints and no history of venereal disease.

On examination there was found to be loss of muscle power, with out evident wasting, in all parts of the left leg. There was painful restriction of movement at the left knee- and hip-joints, but inflammatory signs were absent. As in the other cases, a low irregular fever, with peaks of 101 and 102° F. (38.3 and 38.9° C.), was present, and remained for nearly three weeks. There were no other noteworthy physical signs. Skiagrams of the limb were normal and the surgeon reported that the disability was not an orthopaedic one. On the 24th the patient complained of pains in the eye, lacrimation, headache, and photophobia. He had an acute serous purulent conjunctivitis with episcleritis, but the deeper structures were normal. Two days later an itching papular eruption had appeared on the chest, also involving the penis, and to a lesser extent the abdomen. Benzyl benzoate, applied as a therapeutic test, was ineffective. No organisms were found in the ocular discharge nor could they be at any time. The blood count was normal and the Kahn test negative.

The pains in the leg had almost cleared by the 28th, but some fleeting pains were now being felt in the shoulders. The rash had

spread to involve the whole body except the face, and included the hands and feet. It was only mildly irritating. The individual lesions were small, round, regular, uniform maculo-papules. They involved the extensor surfaces more than the flexor. Two of the papules on the shaft of the penis had broken down and ulcerated; examination of these was negative for treponemata and other organisms. Centrifugal scaling of the individual spots started next day, reminiscent of pityriasis rosea.

On the 30th the eyes felt better, but the sight was "dim." The conjunctivitis had largely subsided, but there was a bilateral circumferential injection with clouding of both corneae, which presented a superficial punctate keratitis. This was treated with atropine drops and a potassium iodide mixture, and there was a slow improvement. By April 30 the eyes were quite clear, and the rash nearly so. The patient was discharged. Unfortunately his eyes relapsed a little over a month later and the rash recurred, though in lesser degree. This time the eyes did not improve so quickly, though partial intermittent emissions occurred. When last seen, in August, keratitis was still present.

Conclusion

It is at least possible that Reiter's disease may occur without one of the three "essential" inflammatory symptoms, but until the causal agent is discovered this is likely to remain a speculation. Incidentally, two of Harkness's six cases of Reiter's disease with keratoderma blennorrhagica failed to show any ocular manifestations. One might, indeed, go further and suggest that perhaps a single symptom may, at times, represent an incomplete form of the whole disease, so bringing forth a possible relationship between Reiter's disease, "non-specific urethritis," kerato-conjunctivitis of unknown aetiology, and "palindromic rheumatism."

The main importance of an awareness of the syndrome lies in its distinction from chronic gonorrhoea, thereby altering the prognosis and avoiding hectic treatment and the venereal stigma. It is probable that Reiter's disease occurs much more commonly than is recognized, but it is considered that the symptom-complex described above is pathognomonic and should usually be unmistakable.

I should like to express my thanks to Prof. Findlay and Prof. Wits for their help in preparing this paper.

Medical Memoranda

Reiter's Disease

In 1916 Reiter described a triad of symptoms characterized by conjunctivitis, urethritis, and arthritis; but very little seems to have been written about it in this country. Colby (1944) said that "Since the initial symptoms of Reiter's disease are frequently related to the urinary tract, the urologist is most apt to see these patients." The intention of his communication was to bring the characteristic triad of symptoms to more general notice. Rosenblum (1945) remarked on the paucity of the literature and the general lack of awareness of the condition. Quite recently Gersh and Reich (1945) described a case of Reiter's disease in a white soldier aged 19. He had conjunctivitis, arthritis, and urethritis.

Such literature as is available stresses the fact that this syndrome, consisting of conjunctivitis, urethritis, and arthritis, may, naturally enough, be mistaken for gonorrhoea or some other condition. In some cases the original diagnoses were rheumatic fever, gout, acute conjunctivitis, prostatitis, acute arthritis, and non-specific urethritis. Because of the lack of information in this country, I think it worth while briefly to describe a case of so-called Reiter's disease which came under my care.

CASE REPORT

The patient was a male German P.O.W., aged 21, admitted with a provisional diagnosis of gonococcal infection not yet diagnosed. Investigations had yielded negative results and he had had sulphonamide therapy. The history stated that the illness started with a cold three weeks before, followed immediately by balanitis, urethritis, conjunctivitis, and painful swelling of the right knee-joint, some slight loss of weight, frequency of micturition, and a fluctuating

temperature. He said that both knees were very painful and that he had had other joint pains; the frequency had settled. In other respects his statement agreed with the written history. He admitted intercourse on a few occasions several months before the illness began.

Examination showed marked bilateral conjunctivitis; both knees were hot, swollen, and tender; he had an abscess on the right calf, boils on the left calf, and a discharging right ear. There was a mild pyrexia. Further examination showed definite keratitis in the right eye, but no perforation of the right ear—external otitis only.

The gonococcal complement-fixation test showed unsatisfactory fixation of complement in absence of antigen. A urethral swab revealed many pus cells, but only a few diphtheroid bacilli were present. No gonococci were seen. A swab from the eyes produced very few diphtheroid bacilli, a few pus cells, but no gonococci. A swab taken after prostatic massage revealed a very large number of mixed organisms, chiefly staphylococci and Gram-negative bacilli, but no gonococci. A full blood count showed: red cells, 4,750,000; haemoglobin, 78%; colour index, 0.82; leucocytes, 11,550. The urine was alkaline with a slight trace of albumin but no sugar. The deposit showed very few pus cells, very few epithelial cells, many triple phosphates, but no casts or organisms.

A German medical officer, also a P.O.W., to whom I mentioned the case, said that it was very common on the Eastern front. It was believed by them to be a virus disease and was usually treated with amidopyrine.

This patient was treated with mist. sod. sal. N.W.F., 1 oz. (28 ml.) 4-hourly; atropine in castor oil, and then penicillin drops, to the eyes. The abscess was incised and drained. Dettol baths were given for the balanitis. The urethral discharge ceased about two days after admittance; the arthritis and balanitis cleared in a few weeks, skin extension having to be applied to the right leg. The eyes were very resistant to treatment and he had numerous relapses. When the right eye was almost clear he had diffuse keratitis of the left eye.

The patient was finally discharged from hospital just over four months after admittance and five months from the first appearance of the symptoms.

My thanks are due to Dr. A. R. Grant, medical superintendent, for permission to publish this case.

F. WRIGLEY, M.R.C.S., L.R.C.P.,
late E.M.S., Whittingham Hospital.

Elongated Styloid Process encountered during Tonsillectomy

In the course of some 450 tonsillectomies performed under local analgesia in adults this is the first case of noticeable elongation of the styloid process I have encountered. It may therefore be considered interesting enough to merit recording.

CASE REPORT

On April 5, 1946, during induction of local analgesia for the removal of small septic tonsils in a woman of 44, the point of the needle encountered a bony prominence at the level of the lower pole of each tonsil. Dissection of the tonsils presented no exceptional difficulty; the plane of cleavage between the capsule of the tonsil and the pharyngeal aponeurosis had to be very strictly adhered to. After removal of the tonsils a pointed and bony-hard prominence could be seen in the lower third of the tonsillar fossa on each side. This prominence was produced by the tip of the elongated styloid process bulging downwards, forwards, and inwards the lateral wall of the tonsillar fossa formed by the superior constrictor muscle of the pharynx, lined on its inner surface by the glistening pharyngeal aponeurosis. Recovery was uneventful.

COMMENT

This moderate bilateral elongation was symptomless, unlike the more pronounced unilateral elongation, of which a case was reported by A. J. d'Abreu (1945), and which was accompanied by discomfort in the neck and throat and displacement of the tonsil.

Elongation of the styloid process is explained by the following morphological facts. The styloid process of the temporal bone, the stylo-hyoid ligament, and the lesser cornu of the hyoid bone represent the stylo-byal, epiphyal, and cerato-hyal portions, respectively, of the bar of the second visceral arch. The stylo-byoid ligament, which is attached to the tip of the styloid process and to the lesser cornu of the hyoid bone, is the morphological continuity of the styloid process, and may undergo partial ossification.

Maunius.

ARTHUR DE CHAZAL, M.S., F.R.C.S.

Reviews

NEW YORK ADVANCING

New York Advancing. Seven More Years of Progressive Administration in the City of New York, 1939-45. By F. H. LaGuardia. Edited by Rebecca B. Rankin. (Pp. 393; illustrated. \$1.00.) Copies available from Municipal Reference Library, 2230 Municipal Building, New York 7.

This handsome and copiously illustrated book is a great tribute to the enterprise of New York City and to the stimulus which Mayor LaGuardia has applied to it during his years of office. We can only single out of the record a few of the city's achievements in the prevention and treatment of disease. Housing is apparently almost as great a problem in New York as it is in London, but during the last ten years the city has housed over 17,000 families of low incomes and proposes shortly to house 18,000 more. Fifty thousand slum buildings have been cleared away. The city's lowest death rate was 9.9 per 1,000 in 1941; it rose to 10.3 in 1944. The best record for infant mortality was when in 1942 there were 28.8 deaths in 1,000 live births; in 1944 it was 31.2, but it is to be noted that the average for the first ten years of the century was 119.9. The record with regard to diphtheria is very striking; thanks to a vigorous and sustained immunization campaign the deaths have dropped from an average of 1,290 a year to 7 in 1944. There is favourable mention of gamma globulin used for the prevention or modification of measles. In a group of 1,000 children exposed to measles, 80% did not develop the disease, while the rest had a very mild attack. The tuberculosis death rate has dropped to 46 per 100,000 of the population. Every quart of milk sold in the city must meet rigid standards of quality and undergo thorough pasteurization. The claim is justifiably made that the city "has one of the most perfect milk supplies in the world."

Hospital building and reconstruction have been partly held up during the war by lack of labour and materials, but the city is now proceeding with a forty-million-dollar programme. Much concern is shown at the alarming decrease of nurses available for city service. Before the war it had 62,000; in 1945 the number was less than 3,000. There is very close touch between the municipal hospitals and the medical schools in the city which has proved fruitful in many directions. An important new development is a forensic institute which will house all the activities of the department of the chief medical examiner, whose function it is to inquire into all doubtful deaths. It will be affiliated to the New York University College of Medicine and will be the centre for undergraduate and post-graduate training in legal medicine. Another novelty is the Bureau of Alcoholic Therapy, instituted by Mayor LaGuardia in 1943 to combat chronic alcoholism. The Bureau "takes the view that the chronic alcoholic is a sick person, his affliction being tantamount to a mental illness. The emphasis of the whole programme is (1) readjustment of the underlying personality defects which results in a perception of values hitherto distorted; and (2) total abstinence, on the assumption that the alcoholic cannot drink in a controlled manner." The therapists employed are themselves ex-alcoholics. The particulars given about the 175 men who have been treated are encouraging. There is no shrinking modesty about the claims made in this record, but the New Yorker may well be proud of it.

PUBLIC KNOWLEDGE

The State of Public Knowledge. By K. E. Barlow. Faber & Faber. 8s. 6d.

Dr. K. E. Barlow's little book suffers from two disadvantages: the first is that its paper and printing have a wartime austerity; the second (common to all philosophical essays) that, unless an author invents words, he is obliged to use common words in an uncommon way. "Integration," the author's favourite word, is an instance. Modern writers overwork it; sometimes it means co-ordination, sometimes harmony, sometimes the absorption of the part by the whole. St. Augustine expressed the stages of human psychology, the transition from the sensuous to ultimate harmony with the infinite, by the words: "De corpore, per corpus, circa corpus, ad se ipsam, in se ipsa, ad Deum, apud Deum." In modern usage this is a succession of "integrations."

A reader might do well to begin with Dr. Barlow's last two chapters; they will encourage him to read the whole book. His insistence on the conceptual nature of scientific knowledge will remind older readers of *The Grammar of Science* which thrilled so many of them forty or fifty years ago. That is not a criticism of Dr. Barlow; it is well that fundamental truths should be restated in the idiom of each generation. Fragments of the idols of the market-place (and of the study) which Karl Pearson smashed fifty years ago have been swept away, but others are worshipped in their room.

To a medical reader, Dr. Barlow's insistence on psychological pattern will be welcome. He takes the example of the intricate pattern of behaviour that such an insect as the hunting wasp *Bembex* follows and must follow. He notes that conscious man may modify his behaviour when the situation changes, but only within limits.

"Carlyle has said in his vivid way," wrote Bagehot 90 years ago, "Two or three young gentlemen have said, 'Go to, I will make a religion.' This is the exact opposite of what the irregular, enjoying man can think or conceive. What! is he, with his untrained mind and his changeable heart and his ruleless practice, to create a creed? Is the gushing life to be asked to construct a cistern? Is the varying heart to be its own master, the evil practice its own guide? Sooner will a ship invent its own rudder, devise its own pilot, than the eager being will find out the doctrine which is to restrain him. The very intellect is a type of the confusion of the soul. It has little arguments on a thousand subjects, hearsay sayings, original flashes, small and bright, struck from the heedless mind by the strong impact of the world. And it has nothing else. It has no systematic knowledge; it has a hatred of attention."

For the "irregular, enjoying man" we may read "every man," for the "two or three young gentlemen" a few powerful men who have shed the blood of thousands, and we have the situation of 1914-18 and of 1939-?. That is Dr. Barlow's case strengthened by evidence not available to Bagehot. It merits our serious attention.

OBSTETRICS AND GYNAECOLOGY

The 1945 Yearbook of Obstetrics and Gynecology. Edited by J. P. Greenhill, M.D., F.A.C.S. (Pp. 576; illustrated. \$3.00 or 18s.) Chicago: The Year Book Publishers; London: H. K. Lewis and Co.

Lest years of war service in distant parts of the earth have been responsible for ignorance which would be otherwise culpable, it is well to remind readers that the *Yearbook of Obstetrics and Gynecology* presents a remarkable summary of the published literature and should be on the desk of every general practitioner and of every doctor specializing in this branch of medicine. The 1945 edition follows the customary plan of being devoted almost equally to obstetrics and gynaecology. The papers to which reference is made are grouped conveniently in sections dealing with pregnancy, labour, puerperium, the new-born, gynaecological diagnosis, operative technique, etc., and there is an excellent double index of contents and authors.

It is interesting from year to year to see how attention is focused on different aspects of the subject in clinics the world over. Some of the published work is original, much of it consists of those reviews of results with the lessons to be learned which are so valuable in assessing the true merit of various methods of treatment. Considerable space is given this year to the subject of ante-partum and post-partum haemorrhage, with particular reference to placenta praevia. An excellent editorial summary helps to guide the inexperienced through the maze of conflicting opinions to the basic fundamental truths. In the gynaecological section vaginal hysterectomy receives some emphasis, and the relevant papers give ample indication that this operation should be more widely adopted. It is distressing to note that the "operative urge" in some clinics is such that the editor, in commenting on their published work, has felt the need to condemn in outspoken terms the tendency to perform hysterectomy for no reason, and Caesarean section with an alarming death rate for conditions such as eclampsia. It is interesting and encouraging to note the dissatisfaction expressed with the results of treatment of cervical carcinoma, for this dissatisfaction is leading to a search for better methods. At least one important American clinic is returning to radical surgery in selected cases as a possible means of improving results.

The *Year Book* is an excellent institution in that it allows busy practitioners to keep in touch with world thought in obstetrics and gynaecology. Dr. Greenhill is to be congratulated on the 1945 edition.

PSYCHOSOMATIC MEDICINE

Emotions and Bodily Changes. A Survey of Literature on Psychosomatic Interrelationships. 1910-1945. By Flanders Dunbar, M.D., Sc.D., Ph.D. Third Edition. With Supplementary Introductions and Additional Bibliography. (Pp. 604. \$7.50 or 50s.) New York: Columbia University Press; London: Oxford University Press.

The appearance of a third edition of Dr. Dunbar's survey of the literature of psychosomatic medicine bringing it up to 1945 is very welcome. In it we can find a mine of useful information culled from the opinions of many leaders of medicine both in America and other countries. It is well selected and arranged, so that there is every opportunity for those who wish to undertake research, which is so very necessary in this field, to get plenty of ideas and those who are perplexed by clinical problems will find authoritative opinions. An extensive bibliography at the end will point the way to further study. It is perhaps indicative of the youth of this branch of medicine that out of 432 pages of text only 11 are occupied by the section on therapeutic considerations.

The main point of this study is that, if medicine as a whole is to be progressive and really promote health and efficiency, the removal of symptoms of disease must no longer be the goal of the physician and surgeon: the patient must be regarded as a whole and his total reaction to the environment must be kept efficient, or if impaired must be repaired. As is very well stressed, the complaint of the doctor going into the Services that he gets no practice in medicine is a reflection on our medical education. What could be better medicine than keeping 1,000 men fit for service in the field and maintaining their morale so that they are ready to face the most violent and disturbing changes in the environment?

In addition to the necessity for further investigation into means of preventing such already well-recognized psychosomatic conditions as peptic ulcer, asthma, hyperpyrexia, and the like the author points out that this field covers such conditions as accident-proneness, liability to colds, and tendency to abortion, etc. In relation to accidents he quotes figures which show that by shifting 5% of drivers with the highest accident records to other jobs the accident rate fell by 80%. Nevertheless this 5 percentage of the employees who were moved to different jobs continued their high accident record, no longer through driving cars, but through slipping, falling, shutting fingers in doors, or in other ways, either at home or in going to and from work. Here there is obviously room for intensive personality studies to the great benefit not only of the individual but also of the community as a whole.

In more difficult cases it would seem that deep analysis is necessary for cure of psychosomatic disease, but in the earlier stages a good deal can be done by the much easier method of suggestion. Unfortunately, as the author points out, the conscious use of suggestion as generally understood by physicians is considered both dishonest and unscientific, being discussed usually in connexion with cults. The "scientific way" is to tell the patient "to buck up," "that there is nothing the matter except his imagination," that he seems to have "one of these troubles we do not yet understand." Clearly it is very necessary to get rid of prejudices and make a concerted effort to prevent and treat these conditions, having regard to the personality of the patient as a whole rather than to the symptoms of which he complains.

Notes on Books

Hereditary Hypochromic Anemia by I. LUNDHOLM was reviewed in an editorial in these columns in 1941, as it was first published as Supplement C 11 to the *Acta Medica Scandinavica* in 1939. It is now available in the form of a monograph (Uppsala: Boktryckeri-aktiebolag; no price given). Its contents are described in the subtitle as a clinical-statistical study, and it provides an extremely useful analysis of the frequency of different signs and symptoms in idiopathic hypochromic anaemia. Lundholm's purpose is to emphasize the importance of constitutional factors in the aetiology, but he has gone too far in renaming the condition hereditary hypochromic anaemia; as well speak of peptic ulcer as hereditary ulceration of the stomach.

Those who saw the recent March of Time film called "Life with Baby" will be glad to possess *How Baby Grows* (Hamish Hamilton Medical Books; 10s. 6d.), a pictorial record of child development during the first five years of life, with a skilful commentary by Dr. ARNOLD GESELL. The natural appearances of the babies and children is most convincing, and parents should find the book a valuable record against which to check the achievement of their own children. It is emphasized that the children chosen represent average trends and that every baby is an individual with his own way of growing up. All workers with children, medical and lay, will find something of value in this excellently produced volume, which attains the usual high standard of publication from Yale and the famous Gesell clinic.

Preparations and Appliances

PENICILLIN OINTMENT FOR OUT-PATIENTS

Dr. I. LLOYD JOHNSTONE, M.C., D.O. Oxon, honorary surgeon, Worcester Eye Hospital, honorary ophthalmic surgeon, Guest Hospital, Dudley, writes:

To overcome the difficulties of dispensing penicillin in the form of an eye ointment for use at home some sort of small container which would not easily become contaminated by non-sensitive organisms and would not affect the potency of the penicillin was required. During the war small porcelain ointment pots were not available, and they are not free from the objection of possible contamination when the lid is removed and a particle of ointment taken for each treatment. The price of such pots would probably be prohibitive.

Penicillin is destroyed by most metallic substances, so that the use of collapsible lead tubes appears to be questionable. There are other well-known collapsible tubes for oculenta and recourse has been made to one of these, namely a glyco-gelatine capsule of roughly one gramme capacity in regular use by Philip Harris, Ltd., of Birmingham, for dispensing eye ointments. These capsules of penicillin ointment have been in use experimentally since March, 1945, and are proving useful within limitations for the purpose for which they were intended.

Three different bases have been tried. The first contained 30% of lanette wax SX, but this irritates some skins. Next anhydrous eucerin was tried, but this had the same objection. This difficulty might be overcome if the pH of the sterilized base were carefully adjusted, but we next turned to a vaseline, lanolin, and liquid paraffin base (30% of each) with distilled water making up the remainder. This does not irritate the skin, but it is quite possible further improvements can be made. Possibly the lanolin could be reduced or omitted with advantage. Finality for the base is not claimed. Strength of penicillin used has been 250 O/u per gramme at first, 500 O/u latterly. The only penicillin used was sodium penicillin made by Glaxo Laboratories. The new British Pharmacopoeia ointment, with only 10% of lanolin and no water, contains 1,000 units of the calcium salt per gramme.

Tests for potency have been carried out week by week with the same capsule of ointment kept in a dwelling house at room temperature. A very small patch of ointment inhibited growth in all directions to a distance of 0.5 to 1 cm. No marked drop in its power of inhibition on the standard staphylococcus aureus was found till the seventh week, when inhibition ceased abruptly following a "heat wave." A further test is about to commence to compare the new British Pharmacopoeia base containing no water with the above base containing 10% of water.

Clinical results are satisfactory so far as the last ointment base is concerned. It is free from undesirable irritation of the skin. The therapeutic effect in blepharitis is variable. Some cases respond well, others not at all. In many cases cultures of the organisms have been grown and sensitivity to penicillin tested, but the quickest and best test is to try either penicillin or thiazamide ointment and change over if the response is not satisfactory. More cases of blepharitis, including styes as well as the chronic scaly and pustular forms of blepharitis, are clinically cured by thiazamide than by penicillin ointment at present.

The Penicillin Clinical Trials Committee of the Medical Research Council has provided the penicillin for this and other clinical research carried on concurrently. Messrs. Philip Harris, Ltd., have very kindly given the full benefit of their experience in making eye ointments and capsules, and have made, supplied, and filled the capsules without charge and on the understanding that they have no restrictive rights to information obtained. Dr. McMenemey and his staff in the Pathology Department of the Worcester Royal Infirmary have carried out the many tests with real interest and enthusiasm. To all these my sincere thanks are tendered.

FOOD CONSUMPTION IN AUSTRALIA

Experience with rationing in this country has so far justified the old-fashioned advice that it is wise to leave the table still feeling slightly hungry. There is no evidence that anyone is physically the worse for shortage of food, and Magee¹ contends that our children, with their special allowances of "protective" foods, are actually better nourished than before the war. Mental preoccupation with food, both our own and that of other people, has, however, become a sign of the times. While hinting gloomily at the direction from which the next cut in our rations is to be expected, some sections of the popular press seek also to incite our envy. Glowing accounts are given of the supposed state of plenty prevailing in more fortunate countries. Thus beefsteak and strong drink abound in Eire, dairy products in Denmark, and asparagus and other choice foods in Northern Italy. Even battered Germany is said to be laughing at us behind our back, cynically contrasting our willingness to endure further sacrifices on her behalf with the thriving state of her own black market. Some of these dreams of rich living may be true, others may not. But in any case the availability of good food for those with money enough to buy it does not necessarily give a true indication of the nutritional status of a whole country. The rich may grow fat while the poor are starving.

In the midst of so much uncertainty it is a pleasure to refer to two official reports, recently issued from Canberra, which give authentic data on food consumption in the Commonwealth are tabulated and compared with similar data for this country and elsewhere. The first report,² issued in 1945 by the Australian Institute of Anatomy, described dietary surveys carried out by that body under the direction of the Nutrition Committee of the National Health and Medical Research Council, Australia. Col. F. G. Goucher was in charge of a team of 15 field officers, who were all women science graduates. About 25 other women were engaged in the compilation of data under Mrs. Isley Gottlieb, and Dr. F. W. Clements was chairman of an Advisory Food Survey Planning Committee. The survey took place during 1944, and in all 2,730 households, comprising 15,235 persons, were investigated. As the survey was limited to households containing 2 or more children, the proportion of children to adults in the groups examined was higher than in the general population. Information on food consumption was obtained through the co-operation of the housewife by means of the log-book or dietary budget method. Data collected from these records were then submitted to statistical treatment, and

figures were converted in various ways to give the mean daily intakes for the many kinds of foodstuffs used and for specific nutrients such as calories, carbohydrates, proteins, fats, minerals, and vitamins. The final values were expressed both for the "adult male unit" and *per capita* and were compared with the allowances recommended by the National Research Council of America. It was fully realized, however, that failure to reach these high standards cannot in itself be taken as evidence of deficiency.

So far as average intakes are concerned the results of the survey indicate that, with the main exception of calcium, Australians during 1944 obtained supplies of foodstuffs and nutrients sufficient to ensure a satisfactory diet. In many instances higher levels of food intake were found than had applied before the war. Thus more fruit and vegetables were consumed, more milk and dairy produce, and, in spite of rationing, more meat and meat products. Equally satisfactory conclusions, however, were not reached in regard to all sections of the population. The vitamin A intake varied considerably according to the amount of vegetables grown in different zones. In 43% of households the intake was less than 70% of the N.R.C. standard allowance, this level being taken as a "restricted" standard in view of the liberality of the original estimate. In 46% of households the vitamin B₁ intake was below the recommended level, and particularly low levels were found in country districts of Western Australia. As in this country, family food intakes were found to increase with income and to decrease with the size of the family.

The second report,³ published in 1945-6 by the Parliament of the Commonwealth of Australia, compares food consumption levels in Australia with those in the United Kingdom. Four Australian representatives, headed by Dr. Clements, arrived in London in September, 1944, and went into consultation with representatives of the Ministry of Food, led by Sir J. C. Drummond. The comparison was made by dividing the supplies of food "moving into civilian consumption" by the sizes of the populations to be fed from these supplies. The committee does not therefore appear to have had access to the results of the 1944 Australian survey. From an account of the statistical methods employed, which runs to 105 paragraphs, the extraordinary difficulty of arriving at strictly comparable estimates of food intakes can be realized. To give only one example, it was necessary to find conversion factors for many foods to relate actual weights to "common denominators." Thus meat was related to carcass weight by a factor which was 1.25 for boned beef, 2.5 for canned corned beef, and 1.35 for other canned meats. Fish had to be treated differently, according to whether it was filleted or whole. Great pains were taken to prevent anomalies arising through the use of different statistical methods in the British and Australian estimates.

The joint committee concluded that during 1944 food supplies were adequate to supply at least the "restricted" N.R.C. standards for all nutrients in both countries, again with the sole exception that the calcium intake was low in Australia. The estimated supplies of some nutrients—including calcium, iron, riboflavin, aneurin, and ascorbic

³ *Food Consumption Levels in Australia and the United Kingdom*, published in 1945-6 for the Government of the Commonwealth of Australia by L. F. Johnston, Canberra, as No. 41, Group 1, F 33, price 3s.

acid—were greater in Britain than in Australia, while the situation was reversed for animal protein, vitamin A, and nicotinic acid. It was clearly stated, however, that the Australian diet was more varied and palatable because of the inclusion of more meat, sugar, shell eggs, and fruit.

Australia's pre-eminence as a meat-eating nation may be judged from the average intake of 212.6 lb. carcass weight per head per annum during 1944, which may be compared with 157.7 lb. for Canada, 155.4 lb. for the U.S.A., and 115.0 lb. for Britain. In contrast Britain led in potato consumption, eating 282.2 lb. per head, as against 190.3 lb. for Canada, 145.1 lb. for the U.S.A., and only 117 lb. for Australia. The Australian's dinner plate, therefore, may be roughly pictured as holding twice as much meat and half as many potatoes as our own. Fish supplies are better in Britain than in Australia, but this advantage must be balanced against inferior supplies of poultry and rabbits.

It is obvious, therefore, that we have good cause to envy not only Australia but also Canada and the U.S.A. for the richness and variety of their diets. We in our turn may be envied by our even less fortunate allies. We must not forget, for example, that until recently inhabitants of Holland poisoned themselves by eating beech nuts, and even tore up their floor boards to make fires for boiling sugar beets. Possibly we should rejoice that we are still far removed from the threat of actual starvation. This source of comfort, however, will do little to allay the growing resentment among our housewives. Often they are tired to the point of neurosis by the intricacies of rationing, by weary waiting in queues, and by the continual strain of planning improvised meals. The slight increase in our meat ration will be welcomed as a small step in the direction of Australian standards of diet, but the voice of the British housewife deserves to be heard much more loudly among those responsible for planning international food policy.

D.D.T. IN GENERAL USE

During the war D.D.T. helped to control the insect vectors of such diseases as typhus, malaria, and dysentery. There was no need to emphasize the importance of this work, and the D.D.T. was properly applied with attendant success. Now D.D.T. is on sale to the public, and it will be used against a wider variety of insect pests and nuisances, but there may be failures and disappointments in store. For example, it is often thought that a few puffs of D.D.T. powder in the wardrobe will protect clothing from moths. But since D.D.T. has no action at a distance and no repellent effect, there is nothing to prevent moth grubs living safely under the lapel of a coat the top of which is covered with D.D.T. dust. A summary of the properties and methods of application of D.D.T. has been prepared by the Ministry of Supply.¹ It should be useful to everyone concerned with insect control.

Pure D.D.T. is a colourless crystalline solid (melting-point 108.5–109° C.), with a low vapour pressure (about 1.3×10^{-7} mm. Hg at 20° C.). It is chemically stable under most normal conditions, so that traces of the substance are very persistent. It is sparingly soluble in water—less than

0.2 parts per million—but soluble in varying degrees in organic solvents. It is least soluble in hydroxylic and polar solvents and most soluble in aromatic and chlorinated solvents. D.D.T. is lethal to a wide range of insects and other arthropods, but the lethal dose varies very considerably from one to another. The dose which will kill a mosquito or a fly is much less than that necessary to kill a flea or a louse, which again are more susceptible than bugs and cockroaches. To be effective the D.D.T., either dry or in solution, must come into direct contact with the cuticle. It is then absorbed and will poison the insect, but the effect is slow and may take from a few minutes to a few days, according to the size of the dose and the resistance of the insect.

Structural formula of D.D.T.

The most valuable property of D.D.T. is its persistence. Surfaces contaminated with it will poison insects which walk over them for many weeks after the original application. To bring D.D.T. into contact with harmful insects it is usually necessary to spread a small quantity of the insecticide over a relatively large area of clothing, walls, vegetation, or water. To achieve this the D.D.T. is diluted with a solid in the form of a powder or with a liquid to form a solution, emulsion, or suspension. It is possible to purchase commercial grade D.D.T. (about 70–80% pure) and make up a suitable preparation from it; but in most cases it is more satisfactory to obtain the finished product from a reputable firm. Such products should give the percentage of D.D.T. on the label.

In the form of a powder, diluted to 5 or 10% with any suitable inert mineral, D.D.T. can be applied against body vermin, such as lice and fleas, against pests of domestic animals, and against crickets, cockroaches, etc. The powder can be dispersed simply by shaking or by means of a "dusting gun." The most commonly used solvent vehicle is kerosene. A solution of 3–5% in this liquid produces a residual toxic film on walls and ceilings to combat such insects as bed-bugs and houseflies. A relatively coarse spray is most successful, since it is necessary to wet the wall; fine atomizing guns create mists which tend to float away. Emulsions and suspensions of D.D.T. in water will also form a residual film. Such preparations have been employed for the control of mosquito larvae and against head lice. It has been shown that D.D.T. can be incorporated in paint or distemper and retain some of its insecticidal power. Its toxicity to insects in this form, however, is much less than that of a superficial deposit, presumably because much of the D.D.T. is buried in the paint. Against flying insects it can be used in the form of a fine mist (aerosol) or a smoke. But these methods do not produce the lasting residual film which is the principal merit of D.D.T.

We have previously^{2,3} reviewed the literature on the toxicity of D.D.T. to man and other mammals. Further results have appeared since then, but they have not substantially altered our conclusions. In insecticidal concen-

³ *Ibid.*, 1945, 2, 260.

trations D.D.T. is practically harmless to man and domestic animals. The most likely dangers from careless use will probably follow accidental or intentional (suicidal) drinking of concentrated preparations, among which may be included the 5% solution in kerosene. There may also be some risk involved in repeated contamination of the skin by oily solutions. These hazards must be considered by pest-control operators, who will regularly handle concentrated D.D.T., but the general public will hardly be concerned with preparations of this type.

The earlier development of D.D.T. was to combat disease vectors and aid military hygiene. In the wider field of plant protection control operations are complicated by the danger of destroying beneficial insects, principally the parasites and predators which naturally keep pests in check. However, this risk has perhaps been overemphasized, since D.D.T. will only do more efficiently what other insecticides have done in the past. The agricultural entomologist is alive to the possibility and will proceed cautiously, keeping an eye on the effects of D.D.T. on the balance of population. The medical entomologist has no such anxiety, since the insect parasites of man are remarkably free from other parasites and predators.

ARTERITIS OF THE TEMPORAL VESSELS

In 1934 Horton, Magath, and Brown,¹ of the Mayo Clinic, reported two cases of an affection they named "arteritis of the temporal vessels." With the recent reports of Kilbourne and Wolff² and Cooke, Cloake, Govan, and Colbeck³ a further 36 examples have been observed, and the clinical picture can now be recognized. The disorder has not been seen below the age of 55, and women are attacked twice as frequently as men. The illness commonly starts with an acute febrile episode, malaise, and muscular pains; in their wake follows a period of ill-health marked by the features of a general toxæmia, low fever, loss of weight, generalized aching, and weakness. This phase may last as long as nine months before symptoms due to occlusion of the temporal artery, or less often some other cranial vessel, indicate the nature of the disease. The spread of the inflammatory process to the temporal artery is accompanied by intense fronto-temporal headache; the vessel may be visibly thickened and the overlying skin red. In many cases pain in the jaw or occiput has suggested that other branches of the external carotid artery were diseased. Two other groups of symptoms have been noted: first, confusion, stupor, or coma, attributed to cerebral arterial disease, though evidence of focal damage to nervous tissue has rarely been found; and, secondly, visual loss, often amounting to blindness—in some of these patients the ophthalmoscopic appearances have been those of occlusion of the central retinal artery, but in many the visual defect has been disproportionate to the visible retinal disease.

The outlook was considered good by those who described the earlier cases, and in the greater number reported the disease appears to have ended in recovery. Doubt has been cast on its benign nature by Cooke and his colleagues, who have recently recorded seven instances, of which three patients died and only one regained good health. In those who have survived, the duration of the illness has varied from three months to over two years.

The morbid anatomy of this condition has excited some dispute. Horton, Magath, and Brown, from the study of an excised segment of temporal artery, believed the process to start as a localized periarteritis and described cellular infiltration in the media and around the vasa vasorum in the adventitia. They considered the lesion to differ from those of periarteritis nodosa and thrombo-angiitis obliterans. Jennings,⁴ recording the first British cases in 1938, found a chronic productive arteritis affecting all coats, with giant cells in the media; he favoured the view that it was a variant of periarteritis nodosa. Gilmour was so impressed by the presence of giant cells that he named the condition "giant-cell arteritis"; it was his belief that the process started in the media. Cooke and his colleagues have pointed out the non-specific character and inconstant presence of these giant cells. These last two papers have shown the widespread nature of the affection. Gilmour found lesions in the aorta, the branches of its arch and their branches; the other authors described them in the mesenteric and femoral arteries. There is general agreement on the obscurity of the cause of the disease; all attempts to isolate a causative organism have been unsuccessful.

There is now abundant evidence that the syndrome of "temporal arteritis" must be regarded as the local expression of a specific generalized disease of the arterial system and the experience of the Birmingham observers justifies their comment that it is "not uncommon but rarely recognized."

SELF-PROTECTION IN THE STOMACH

The mechanisms underlying the development of chronic peptic ulcer in man remain enigmatic. Two facts, however, are not in dispute—that the condition is extremely common as a cause of chronic dyspepsia among the populations of Europe and America, and that treatment is still far from satisfactory. From time to time enthusiastic reports in the medical journals suggest that a solution to the problem of treating peptic ulcer has been found. But in a disease so prone to spontaneous remission of symptoms and so intimately associated with psychological factors, assessment of results is notoriously difficult, and none of the claims previously made has survived the test of prolonged and carefully controlled experiment. Nevertheless, any reported success for a new method of treatment deserves attention, and two recent papers by Morrison⁵⁻⁷ suggest a promising line of investigation.

Working on the assumption that the gastric juice might contain a substance which protects the gastric mucosa from self-digestion, Morrison treated ten patients with radiologically demonstrable peptic ulcers (five duodenal, three pre-pyloric, and two gastric) by the administration of normal gastric juice obtained from healthy volunteers. The gastric juice was removed at 15-minute intervals over a period of three hours, after the subcutaneous injection of two doses of histamine, 1 mg., one hour apart; the first specimen was discarded, and subsequent specimens, in which the concentration of pepsin and mucin was low, were pooled, rendered neutral by sodium hydroxide, filtered, and preserved with 0.3% tricresol. This was then administered, in doses of half an ounce diluted with 2 oz. of tap water, every hour during waking hours to the patients with peptic ulcer. No other medicament of any kind was given, and the patients remained ambulant and on a normal diet. Smoking was allowed, but alcohol was forbidden. Two of the patients, the previous duration

⁷ *Ibid.*, p. 328.

of whose symptoms was 19 and 25 years respectively, showed no improvement during three weeks' treatment. The remaining eight, who had had symptoms for periods varying from one to thirteen years, all showed relief of symptoms within 24 to 48 hours and disappearance of radiological evidence of ulcer in 10 days to 3 weeks, and had remained free from recurrence for three years.

Morrison's second paper deals with the prevention of experimental peptic ulcer in dogs by the administration of a preparation of hog stomach. Each of two groups of dogs was given 2.5 grammes of yellow cincophen (phenylquinoline carboxylic acid) daily by mouth: this substance has been found by many investigators to produce chronic peptic ulcers, indistinguishable pathologically from those occurring in man. In the control group of ten dogs chronic peptic ulcers were produced in all cases, being multiple in five animals: the ulcers were produced within six weeks in nine of the dogs and within four months in the tenth. In the second group, of twelve dogs, 1/2 lb. of a preparation of the mucosa and submucosa of fresh hog stomach and duodenum was fed to each animal daily, and the dogs were sacrificed at intervals up to four months, one dog being killed at the time of each death in animals of the control group. No peptic ulcer was found in any of the second series of dogs, though some degree of gastritis was present in eight of them.

It is to be hoped that other investigators will undertake research along these lines. There is no lack of clinical material, and if Morrison's therapeutic results can be confirmed in a larger series of patients, with adequate controls, a new and promising field of study will be opened up.

WELFARE SERVICES UNDER THE RED CROSS

After the first world war the national Red Cross Societies in this and other countries, with their raised prestige and enlarged place in public affection, took up a number of activities in addition to the continued relief of those suffering as a direct result of war. These included, in Great Britain, various forms of hospital social service, ambulance work, the training of nurses and auxiliaries, popular health instruction, and child welfare. This time the British Red Cross Society contemplates an even larger and more closely defined peace programme. The great momentum which the Red Cross and St. John Organization achieved during the war is by no means spent. Under the terms of its supplementary charter the British Red Cross Society is empowered to assist the civil population in any manner calculated to promote health, prevent disease, or mitigate suffering. Accordingly a special department of welfare services has been set up, the primary purpose of which is to supplement the work already done throughout the country by voluntary organizations and statutory bodies. Three sections are proposed—one for welfare work among and after-care of the civilian disabled, including presumably those wounded in industry, an army whose numbers have never been adequately assessed; another for the care of invalid and crippled children; and the third for the care of the aged infirm. The supplementary nature of this work is emphasized—for example, the care of invalid and crippled children will be undertaken in association with the Central Council for the Care of Cripples, the Invalid Children's Association, and similar bodies.

This Red Cross effort is not concerned with the creation of a new organization but the assistance and reinforcement of such organizations as exist. The newly appointed director of welfare services is Dr. Harold Balme, who will continue to act as medical officer in charge of rehabilitation to the Ministry of Health, but on a part-time basis.

Already various forms of welfare services have been started by members of the Society in different parts of the country, and the co-ordination of these will be one of Dr. Balme's principal tasks. The mere existence of the new department will probably bring a large accession to the ranks of such workers. Plans will be made for their training, because training to the Red Cross worker, whether for peace or war tasks, is more than half the battle. At the same time the various forms of welfare work undertaken by the Joint War Organization of the British Red Cross and the Order of St. John on behalf of men and women in the Forces or invalidated therefrom will go on under joint committees set up for the purpose, and the emergency help committee, also a joint organization, will continue to give financial and other aid in cases of need among war pensioners. Thus the fine work done in war will be repeated and carried on in the less exciting but not unadventurous fields of peace, and no doubt when the programme of activity comes to be formulated new occasions will present themselves and new duties be undertaken on behalf of distressed and disabled members of the community.

SEQUELS OF KERNICTERUS

That kernicterus might be responsible for many clinical syndromes of childhood and adolescence is becoming recognized.

A demonstrable mother-child Rh incompatibility in neuro-psychiatric syndromes provides suggestive support to this conception. We recall the study made by H. Yannet and R. Lieberman,¹ who found that incompatibility of this kind occurred more often among undifferentiated defectives than in a control group of organic amentias and dementias. The same authors² have carried their earlier investigations somewhat further. A series of 277 defectives (with I.Q. less than 30) was available, with maternal blood samples to hand. Of these children 158 belonged to well-defined diagnostic categories, such as mongolism, diplegia, post-traumatic sequelae, and this number was used as a control group. The remaining 119 were regarded as undifferentiated defectives, though it was pointed out that inadequate data and case-histories might have resulted in the inclusion within this series of a number of "organic" cases. In the control group 22, or 14%, of the mothers were Rh negative, a figure which corresponds with a basis of random selection. According to W. T. J. Morgan³ a Rh negative woman has a 60% chance of giving birth to a Rh positive child. Hence the 22 mothers might be expected to have 13 Rh positive children—that is an 8.2% random ratio of mother-child Rh incompatibility. The actual findings in the authors' control group were 12 instances out of 22, or 7.6%. Amongst the undifferentiated cases, however, 26 (or 22%) of the mothers were Rh negative. One would expect to find in such, 15 or 16 Rh positive children; actually there were 19, or a 16% incidence of mother-child incompatibility. The difference between the two ratios (16% and 7.6%) is statistically significant.

This report tallies with the findings of L. H. Snyder, M. D. Schonfeld, and E. M. Offerman,⁴ who found almost twice as many instances of Rh incompatibility in a series of 68 undifferentiated mental defectives than random selection would have warranted. A similar study of cases of high-grade defect and minor neurological abnormalities might have yielded even higher figures than those of Yannet and Lieberman, whose patients comprised only idiots and imbeciles.

TYPHOID AT ABERYSTWYTH

A first case of typhoid fever was admitted to hospital on July 27 at Aberystwyth. Other cases followed, and confirmation of the clinical diagnosis was obtained in the first case by a positive Widal test. All the cases were of a mild character. Headache was usually complained of at the onset, and there was a high temperature and no very clear-cut clinical findings. The first 22 patients were questioned carefully, and it was found that all of them had eaten ice-cream from the same source. The only other factor common to all cases was water, and both water and milk supplies in the area concerned had already been tested, with negative results.

By July 29 it was clear that the infection had been conveyed by a single barrel of ice-cream. The man who had manufactured and sold it was immediately placed under observation. A Widal test was positive 1:320, and on July 30 a test against the Vi antigen of the typhoid bacillus was positive 1:80. He gave a history of having had typhoid fever in 1938, and the bacteriological findings strongly suggest that he is still excreting the *B. typhosus*. The following statement was issued on August 4 by Dr. D. I. Evans and the Mayor, Alderman H. G. Pickford:

Every certified suspect is being taken into hospital for observation, and in every household affected the members have been instructed as to precautionary measures to be taken. So far as can be traced no single case has occurred outside the original source of infection, which was ice-cream. The milk and water supplies are satisfactory. The town medical authorities are having the fullest support from the county medical authorities and from the Welsh Board of Health, and every precaution is being taken to prevent the spread of infection.

We are informed by Dr. D. I. Evans, who is the part-time M.O.H. for the Borough of Aberystwyth, that up to August 6 there were 51 admissions to hospital from the borough itself, and in most, but not all, of these cases the diagnosis of typhoid fever had been confirmed bacteriologically. Other cases have been notified in the districts just outside Aberystwyth.

The local isolation hospital is now full and arrangements have been made for any additional cases to be sent to hospitals outside the area. The cases so far are mainly among women and children, and it has been reported in the lay press that there are no visitors affected. At the same time, practitioners throughout the country should be aware of the Ministry of Health view: "It is feared that the disease may occur in holiday-makers who have returned to their homes in other parts of the country." It seems that secondary cases are now appearing, and therefore the likelihood of cases arising in places far removed from Aberystwyth is the greater. In view of the fact that the primary source of infection was not stopped until July 29 further cases may occur up to the middle of August.

An appeal to local authorities to intensify their efforts to ensure larger uptake of the welfare foods which have proved so important to the health of expectant mothers and young children is made by Rt. Hon. Joseph Westwood, M.P., Secretary of State for Ireland, in a Department of Health circular. The Government has decided to continue the welfare foods scheme for expectant mothers and young children as a supplement to the family allowances scheme. The welfare foods scheme, however, is not being restricted to families entitled to a family allowance. The foods will remain as at present, milk—liquid milk or, alternatively for infants, national dried milk—orange juice and cod liver oil, or vitamin A and D tablets in place of cod liver oil for expectant mothers. There will be no change in the quantities to be made available. But liquid milk is to be available under the scheme at a cost of 1½d. a pint instead of 2d. a pint; the price of national dried milk is reduced from 1s. 2d. to 10½d. per tin; and cod liver oil—or vitamin A and D tablets—is obtainable free. Free milk and orange juice will be allowed automatically to people receiving public assistance or payments from the Assistance Board. Local authorities are notified that application forms for free milk and orange juice can be obtained from the Ministry of Food if they wish to have a supply for women in their area at, for example, maternity and child welfare centres. In a circular to welfare authorities in England the Ministry of Health draws attention to the Government's decision to continue the existing welfare foods scheme with some slight modifications, as a supplement to the family allowances scheme, though the welfare foods scheme is not being restricted only to families which are entitled also to a family allowance. The welfare foods scheme has proved its importance to the health of expectant mothers and young children and full advantage should be taken of it. The Minister therefore asks welfare authorities to intensify their efforts to ensure a larger take-up of the welfare foods.

Correspondence

The Plebiscite

SIR,—The Representative Meeting of the British Medical Association has decided, and quite rightly, to take a plebiscite of the profession. It is to be regretted, however understandable, that there should have been uncertainty and some confusion over the terms of reference. We are approaching the most crucial moment in the history of British Medicine, and it is absolutely vital that the terms of reference should be crystal clear, so that no doctor can be in any doubt as to what he is being asked to decide, together with all the implications of that decision. The Health Bill is now past its Third Reading, and it is obvious that any changes will be in matters of mere detail only. The ring fence described by Dr. Dain is complete, and the medical profession is invited to walk in. Upon the main structure—the central and general organization, hospitals, Ministerial powers, direction of doctors, sale of practices, and so on, and so on—upon such as these the profession has not been, and will not be, consulted, nor was it ever intended that it should be. Our negotiators are invited to negotiate—but it will be upon matters of detail, upon regulations which the Minister may make, upon terms of service.

Herein lies the danger. Many may say: "What harm can there be in that, if we can do so without prejudice?" Unhappily, and this is particularly true in dealing with the Government, there is no such thing as "without prejudice." It has been shown time and time again, and it needs shouting from the house-tops at this moment, that it is impossible to negotiate on detail without at the same time conceding principles—those principles which the representatives of the profession have affirmed, and reaffirmed, as fundamental. Once we are committed to discussion of detail, the flank of principle is turned, and our position becomes untenable. There is no recovery.

If any man still doubts that the Government intend to pass and to implement the Health Bill as it stands, let him read the nauseating statement with which Mr. Bevan concluded his speech on the Third Reading. In such circumstances, and having ensured by personal contact that doctors are fully aware of the implications of their action, the question to each should be just this, "Are you prepared to enter the Government Health Service as it stands?"—answer, "Yes!" or "No!"—I am, etc.,

Dr. D. I. Evans.

E. D. BROSTER.

Health Service Bill

SIR,—There has been a disquieting silence on the part of the leaders of the medical profession concerning the policy, if indeed they now have a policy, which they would recommend the rank and file to adopt *vis à vis* the National Health Bill, soon to become an Act without the adoption of any but minor amendments. The appearance of so many letters on the subject in the *Journal* demonstrates the continued interest of the profession in the subject, even if the variety of opinions expressed approximates too closely to the number of writers.

Why this prolonged silence? Is it because with Machiavellian guile the Minister of Health has succeeded in dividing the profession against itself, favouring the Universities and teaching hospitals, granting the latter privileges that he denies the non-teaching hospitals, at the same time promoting the dictatorial attitude which so many good men and women so easily acquire?

Were we wise in seeking to have so much decided at the regional level? Have we so little trust in, and so little influence on, the men and women among whom we live—and from whom our incomes are derived? Surely this is a defeatist attitude? If we cannot influence our neighbours, what prospect is there of influencing a more distant body and making it aware of our local needs?

A great danger of the Bill is that it aims at stercotyping the country's medical services. The Minister of Health, as the grand panjandrum, will direct the specialists of the teaching hospitals, the *prima donnas* (the Minister's description),

*Ediswan Convulsion**Therapy Equipment*

Many hospitals and medical institutes throughout the world are equipped with Ediswan Shock Convulsion Therapy Appliances and Electro-medical apparatus. For full details of these products and any particular requirements, write to:—

IN DEFICIENCY DISEASES **MARMITE** YEAST EXTRACT

The P.O.W. and internee have perforce become food conscious and have come to appreciate the significance of quality as well as quantity; many of those who have been in the Far East have suffered particularly from deficiency syndromes associated with shortage of vitamins of the B₂ complex. For these cases Marmite is especially valuable, as it provides a means of contributing just these factors in useful amounts—and their presence together in a natural product possesses distinct advantages.

1-oz. of MARMITE provides
Riboflavin (vitamin B₂) 1.5 mg.
Niacin (nicotinic acid) 16.5 mg.

Obtainable from Chemists and Grocers
Special terms for packs for hospitals and welfare centres

Prevent Discomfort

IN HAY FEVER AND SUMMER COLDS

To the hay-fever victim the use of 'Benzedrine' Inhaler may make all the difference between weeks of acute misery and weeks of comparative comfort. Its vapour diffuses throughout the entire nasal cavity and is strikingly effective in reducing the intense congestion which makes allergic rhinitis so distressing.

Head colds are particularly annoying during the summer. 'Benzedrine' Inhaler helps to cut them short and provides welcome symptomatic relief.

Each tube is packed with Amphetamine (B.P.) 325 mgm.,
Oil of Lavender 97 mgm., Menthol 32 mgm.

who in turn will direct the rest of the ballet, consisting of the medical staffs of the non-teaching hospitals. In this performance the general practitioners are to be relegated to the position of supernumeraries, scene-shifters, and such like.

Now no medical service will be satisfactory unless the general practitioner is satisfactory. Properly educated and organized for his work, not only would he deal more satisfactorily with early illness and thereby make much hospital treatment unnecessary, but could engage in much at present neglected research work, which probably cannot be, and certainly has not been, done in hospital. Illness has an ante- and a post-hospital stage, and until that is fully recognized and acted on there will continue to be a deplorable amount of chronic illness.

I think the account of the grand panjandrum ended "and the gunpowder ran out of his heels," or was it boots? If the Minister of Health pursues his present course he will find his gunpowder similarly run out. I suppose it is too late for the slogan "Negotiation not dictation" to be effective.—I am, etc.,

London, W.8.

HAROLD H. SANGUINETTI.

SIR,—I trust that now the Committee Stage of the National Health Service Bill is completed Council will give us a definite lead. The road to hell is paved with good intentions, and "intentions," and those on minor points, rather than "promises" or "changes," are all the Minister has conceded, according to your analysis of the Bill's Committee Stage. (*Supplement*, July 20, p. 13.)

The profession is in a state of bewildered frustration. Few, I believe, like the Bill. The majority are apathetic, resigned, or ignorant. We have had to refrain from playing the Minister's game by fighting shadows, but now he is committed and the issues are becoming clear.

Let us not now cloud the fundamentals by discussing terms of service or details of administration. Our seven points can be converted into something concrete—e.g., the removal of direction, the removal of the penal clauses, etc. The issue is freedom, and with a proper lead now a large part of the apathy will go. Let our consultant friends remember that theirs may be, at present, a gilded cage, but it is a cage nevertheless, and the Minister is not unaware of the maxim *divide et impera*.

The contumely with which this Minister has from time to time treated the profession and its representatives makes it certain that no satisfactory arrangements which will be respected by him or his successors will ever be made until he has been fought and beaten on some major issue. He has to be converted from his Fascist concepts by a wholesome course of medical discipline.

The time for fighting is now. We have the power; the public believe we have the power. Let us not have feet of clay.—I am, etc.,

Wolverhampton.

ROBT. S. V. MARSHALL.

SIR,—There is one point about which many of us are concerned at the present time. This is the question of victimization of members of the profession as a result of impending legislation. There are many men who are either bound to lose a portion of their income or, in the case of certain specialist branches, to lose the whole of the capital value of a purchased or carefully built-up goodwill, without hope of compensation, if some sort of safeguard is not provided.

Whatever view any medical man may take of things to come, either antagonistic or laudatory, the profession as a whole would be solid in fighting rank injustice. If the B.M.A. takes the attitude that, as an essential preliminary to accepting and recommending Government proposals to the profession, a tribunal of suitable composition should be established to guard against what amounts to a total capital levy, it would have the profession behind it to a man.

No trades union would allow, or be permitted to allow, victimization of a single one of its members in coming to agreement with the political caste—for caste it is.

This is not a question of politics but plain justice. Even a criminal is not deprived of his all. One can only surmise that some of us, having dared to enter the profession and develop certain branches in advance of State provision, have

somehow qualified as superior criminals, whose professional goodwill can just be confiscated by the bureaucratic machine. If the B.M.A. does not stand firm on this point it will not only lose our respect but many of its members.—I am etc.,

London, S.E.5.

GUY BOUSFIELD.

The Public and the Bill

SIR,—Mr. Aneurin Bevan, the Minister of Health, must be none other than Mr. Bevan, the Minister of Housing, who forgot to order the bricks. He has offered the public a complete national health scheme to start in 1948, but he has forgotten the medical personnel. It is quite definite that two or three times the present number of doctors and nurses will be required if the Minister is to fulfil his promises, and yet he has cut off the supply of new recruits at the source. By pouring scorn on the voluntary system with its flag days and its charity he has cut down subscriptions to the larger hospitals, which had to close wards as a result, and by describing the smaller hospitals as inefficient and unfit for the training of nurses he has caused the junior staff to leave these hospitals, with the result that they have had to close.

The medical student is to be called up in just the same way as other boys, and the result is that many of these will not feel inclined to undertake the long and tedious course which is required, when they have finished their military service. Surely it would have been wiser to have let the medical student carry on with his studies when he left school and do his military training at the end of his course, when he is a qualified doctor? The Services will require doctors, and so many will have to do their service both before and after their medical course. I think the public should know these facts, as they are shortly to begin paying very large weekly sums for something of which there is little hope of fulfilment.—I am, etc.,

Camberley.

LESLIE HARTLEY.

Direction under the Bill

SIR,—There are many who approve of a National Health Service. There are many who do not. But on the issue of direction there can be no Britishers who are not against it. No amount of side-tracking can get over the following: If a man enters the Service he can be directed; if he does not enter, as he cannot use the hospitals, he will starve. The matter is really national, as well as personal, and if we doctors, in summer, cannot spare time to point out to our patients that Magna Carta and its amplifications are nearly strangled, then we deserve to suffer the loss of personal freedom. We must somehow find the time and energy to get every patient who is against the National Health Service, or has doubts, to write to the Prime Minister. Then get the local M.P. to ask in the Commons the number of these letters, and force an honest reply. If we do the job well, the number, I believe, will be a good half of the adult population, and if our servants of State (so-called) choose to ignore that number, then the Press will do the rest of the job.

To those practising in predominantly Labour areas: point out to the individual that there isn't any risk of indirect punishment via the T.U.C., as even this Government hasn't enough spies to do that.—I am, etc.,

Stamford.

A. HENRY GREGSON.

Hours of Work under the Bill

SIR,—We have still no information from the Minister of Health, nor from the Negotiating Committee, as to what hours of work per day, or week, are proposed for the State Service. Remuneration, as in other services, must be related to hours worked, off-time periods, and pay for overtime. Without this information it is impossible to evaluate the remuneration, or answer anything in the way of a referendum.

One cannot suppose that the Ministry will require us to work a twelve-hour day with no week-ends off and two weeks' holiday in the year, as at present many of us do. Such doctors' hours of work are those of the worst period of the Industrial Revolution. May we have this very necessary information from someone, please?—I am, etc.,

Birmingham.

W. J. BURNS SELKIRK.

Regional Hospital Services

SIR,—The regional hospital scheme of the Health Service Bill aims at remedying defects in the present hospital services. Most of these are traceable to want of co-ordination between institutions, to want of co-operation in the public interest. History is our warrant for saying that the successful schemes of public service have been those in which a primary and basic purpose has been clearly seen and consistently followed; that on the other hand the failures have been those in which secondary considerations have been allowed to interfere in the making of the scheme's pattern.

There will be no quarrel with the dictum that the satisfaction of public need should be the basic purpose of this scheme and should dictate its pattern without serious interference. This purpose would have had a fair prospect of being fulfilled if a directing regional board, experienced in public administration and finance, had been given control of all hospitals in an area, subject to an obligation to consult the governing body of a university medical school on questions that concern the appropriate use of institutions, the sharing of duties between them, and their medical staffing. In the Provinces this is not to be the plan.

Regional boards will all need, to complete their schemes, a group of central institutions manned by the most experienced consultants and specialists, to serve as a last court of reference for patients who present the most difficult problems of investigation and treatment. The plan of the Bill withdraws from the direction of regional boards the institutions that are best equipped for this function, and sets them apart under separate governance on the ground that they are to fulfil a special function, that of teaching. The selection of patients for admission to these "teaching hospitals" will presumably be based upon the carrying out of this duty, which is the reason given for their segregation. This is surely an example of allowing a secondary obligation to mutilate a scheme to the serious detriment of its primary obligation.

I cannot, in any space that you, Sir, could allow me, mention all the difficulties and disadvantages that this division of authority is likely to create. Under such a uniform scheme as I have envisaged, the medical schools would, with the support of the Ministry, have had no difficulty in obtaining the teaching facilities that they need for their students. The means that the Bill offers them are not only clumsy and insufficient from the administrative point of view, but also cut across the prospect of a service that will give what the public needs. Incidentally, it recreates and stereotypes caste distinctions between hospitals, which have been one of the chief defects of the past system, or want of system, and which every wartime hospital administrator had good reason for recognizing as such.

No material change in the Government plan is now to be expected, but when those who elaborate it discover that there are not in the provincial centres any "teaching hospitals" comparable to the teaching hospitals of London which house, maintain, and direct medical schools, what then? Medical faculties and faculty boards are the only bodies which possess the experience necessary to give expert advice to regional boards on the professional matters mentioned above; is the allocation of them of this duty and privilege possible within the Bill's framework?—I am, etc.,

Liverpool

K. W. MONSARRAT.

An Aspect of Government Salaried Service

SIR,—In view of the threatened salaried service that is upon us, I would like to call attention to a previous situation when medical practitioners were paid salaries for full-time State service under contract to the Government; especially as in conversation with my colleagues in various departments of medicine I found few who realized that such a sequence of events had taken place.

In September, 1939, many resident medical officers were virtually "drafted" into the Emergency Medical Service. I believe that a very high percentage of these medical officers accepted the posts gladly, and with a great deal of willingness to do their utmost under any circumstances in the threatened devastation by air attack on their country, and were unconcerned by considerations of the salary that might be meted out to them, provided they were reasonably fed and housed in accordance with conditions that might prevail under total

war. Many were gratified at the princely sum of £350 per annum, plus board and lodgings, that they received under Government contract, and which was indeed a financial satisfaction to those who at the time were only receiving £50 and keep for full-time services; thus they were able to undertake domestic commitments in accordance with their age and station in life which would otherwise be prohibited owing to finances. Approximately six months later, however, when Britain had not suffered the hardships that had been anticipated, these same M.O.s were asked to waive their contracts and accept £200 per annum, a reduction of salary of over 42%. The penalty for not conceding to the request was appointment to another area, usually more uncomfortable, with its attendant personal and professional inconveniences, or drafting to military service. This time a direct contract was not given to the M.O., but he was paid from a central pool, often very much in arrears and with no contract or guarantee that his income would remain stable for a greater length of time than three months. Soon after this the major blitz on Britain commenced with numerous areas affected, entailing very continuous and arduous work for this class of M.O. and no reinstatement to the £350 basis. The first generalized blitzing of Britain quietened down considerably by the summer of 1941, and within three months the same class of M.O., on appointment, received remuneration to the extent of £120 per annum, a further reduction of 40% from his immediate predecessor, and a total reduction of over 65% of what the Government had originally contracted to pay one class of its employees.

Admittedly this occurred during a national emergency, and any hardships due to these reductions would be willingly undergone, except, if the public press is to be believed, that most other employees on essential services did not have to share these financial "cuts," in spite of the fact that they had not had the years of training and personal monetary outlay in acquiring the skill for specialized wartime employment, therefore presumably would be better able to stand reduction. Were these reductions only made on the medical profession because they were unlikely to strike, as opposed to workers who have since shown their irresponsibility by striking, and thus have been able to demand their "rights" and maintenance of remuneration and comfort?

I agree that all this is a hatchet that is best left buried, and the necessity of bringing it into the light at all only occurs when a similar situation may be allowed to reappear through insufficient warning to enough of the people concerned. It has been cited that the Government, from the financial standpoint at any rate, will not be stinting in their remuneration of the State doctor, but what value can be placed in their contract, especially when they are spending such "global" figures? Will they not have to cut their expenditure some time because the taxpayer cannot, or will not, stand the pace or the Treasury cannot afford it? How will they begin to economize? Will they reduce the doctor's scale of capitation fee or basic salary, because he will carry on his job in spite of it? Or the standard of equipment required in hospitals? They will continue to aid the sick, too. Or will they economize in the wages of the industrial workers, who have been known to lay down their tools when they have a grievance?

Please do not think that my only objection to State medicine is on the financial side, for I am entirely opposed to a lay dictatorship of medicine on the totalitarian system, and honestly believe that politics and trade unionism are best left to those who have not been acquainted with the Hippocratic oath. My feelings have already been stated more adequately than my ability to express them by others of your readers, but hitherto I have not seen this particular aspect brought up.—I am, etc.,

Wheatthampstead.

C. F. C. PARKINSON.

Black Tongue and Oral Penicillin

SIR,—We read with great interest the letter on this subject by Dr. P. D. Bedford (July 13, p. 63). We should like to bring to your notice that two cases of "black tongue" were reported at the meeting of the Royal Medico-Psychological Association on Feb. 14, 1946, by one of us (F. M. S.).

One was observed after oral administration of sulphadiazine and the other of penicillin. The local effects were similar to those described by Dr. Bedford, and the penicillin case showed in addition distinct symptoms of nicotinamide deficiency—such as skin changes, sensory disturbances in the legs, abdominal pains, general fatigue, inability to concentrate, and memory disturbances. In the latter patient it was also possible to reproduce the same symptoms with a second course of oral peni-

cillin and to examine the nicotinamide status simultaneously. The level of nicotinamide methochloride in the urine before penicillin was given for the second time was low but above the deficiency level. It fell considerably during dosage to a level indicating a deficiency. After discontinuing penicillin the nicotinamide methochloride level rose higher than before. When at this high level penicillin was given orally for a third time the nicotinamide methochloride output did not fall below that of the nicotinamide deficiency level, and no local changes were observed on the tongue; and only very mild general symptoms were experienced. These findings indicate that oral administration of penicillin can cause a nicotinamide deficiency, as has been found after oral administration of succinyl sulphathiazole or sulphaguanidine by one of us (P.E.) and by Hardwick, by their action on the intestinal flora. Whether the black-tongue symptom, which is rare in human but common in canine nicotinamide deficiency, is partly due to an additional local effect of penicillin on the tongue has still to be investigated. The details of our findings will be published in due course.—We are, etc.,

The "Intractable" Vesico-vaginal Fistula

SIR,—The correspondence on this subject is of deep interest to all who have the management of these difficult cases under their care. I am without experience of the conditions existing in Bantu, but in this country there are other fistulae which occur in the bladder at a higher and more lateral level than those located near the urinary meatus; these may involve the ureter as well as the bladder. They are not suited to the approach of Marion Sims.

I would draw attention to an alternative to colonic transplantation, and that is the suprapubic transvesical approach. The bladder is opened by an adequate incision, as in suprapubic prostatectomy, the access afforded is good, the technique is not difficult. In addition to the ordinary case, multiple fistulae are readily closed, and ureteric damage remedied by transplantation of the divided end into the bladder. In all cases the operation concludes with suprapubic bladder drainage. This technique originated, I believe, with the late Mr. Swift Joly, and if it is adopted I cannot think that many cases will call for repeat operations nor for colonic ureteric transplantation.—I am, etc.,

London, W.1.

EVERARD WILLIAMS.

Carcinoma of the Bladder and Vesical Calculus

SIR,—Since 1833, when Bayle first drew attention to the relationship between bladder calculi and tumour, calculi have frequently been described in association with bladder tumour. Ash (1940), however, in a study of 2,743 cases of carcinoma of the bladder recorded that in no case could he find any association of a calculus with the formation of a bladder tumour. In a recent investigation which I carried out on 189 cases of bladder tumour treated at the Cardiff Royal Infirmary, 6 of the cases had a history either of having passed stones *per urethram* or of stones having been removed suprapubically prior to the appearance of the symptoms related to the tumour. There was no direct evidence in any of the 6 cases that the calculi were the exciting factor in the production of the tumours. In one other case, however, there was more definite evidence that the bladder tumour may have been due to the presence of a stone.

Case History.—The patient, a male aged 57, was admitted with acute retention. He gave a history of haematuria and frequency of four years' duration. Cystoscopy was impossible. At suprapubic cystotomy I removed a large calculus, the size of a walnut, which had become impacted in the internal urinary meatus. After removal the base of the bladder was inspected but no obvious lesion was observed. There was certainly no obvious tumour growth. Six months later he was readmitted with haematuria of three months' duration. At operation a papillomatous growth was found surrounding the internal urinary meatus at the site where the stone had previously been impacted. Histologically the tumour was a papillary carcinoma with very marked squamous metaplasia present.

Squamous metaplasia in papillary carcinoma was seen histologically in 7 of the tumours of my series, and in all of these tumours there was marked histological evidence of long-standing inflammation. Clinically, 4 of the 7 cases gave a history of chronic renal tract infection over a period of from three to ten years; in the other 3 the history of infection was much more recent. I personally feel that though there is uncontroverted evidence that chronic irritation, whether in the form of chronic infection, or of a calculus, or of vesical schistosomiasis, does produce bladder tumours, yet in a number of cases the squamous changes are secondary and arise in a tumour which is already present in the bladder.—I am, etc.,

Cardiff.

Drug Eruption after Sodium Pentothal

SIR,—Drug eruptions due to sodium pentothal, as Dr. G. A. Grant Peterkin (July 13, p. 52) points out, must be exceedingly rare. After using the drug for seven years I had never seen any form of eruption until two weeks ago.

The patient had a tuberculous lung and a hysterectomy for fibroids was to be performed under a spinal anaesthetic. The patient, wishing to be put to sleep, was given 10 ml. of a 5% solution of sodium pentothal and then turned on her side for the administration of the spinal anaesthetic. Within a few minutes and before any antiseptic had been applied to the back, large urticarial weals occurred on the back and quickly spread all over the body. Her eyelids swelled considerably and her lips to a small degree. Fortunately no swelling of the tongue occurred.

The operation was proceeded with under light nupercaine and as the patient was restless a few more mls. of pentothal were given. At the end of the operation all the urticarial weals had subsided but the eyelids were still a little swollen. Next day the patient was quite well.—I am, etc.,

Bristol.

R. HASTINGS MOORE.

Total War on Cancer

SIR,—In his interesting paper on this subject (July 20, p. 77) Mr. G. F. Stebbing omits to mention one valuable line of attack and research. It was known to witches, and is a matter of scientific observation to-day, that intractable cutaneous papillomata of many years' standing are curable by suggestion. This discloses the fact that the body can produce, or be persuaded to remove, some simple new growths by activities engendered in the psyche. Emotional states also are known to be a source of variation in the chemistry of gastric secretions. When, therefore, Mr. Stebbing writes "Cancer starts in every case with a single cell or group of cells in the body that revolt, as it were, against the general system," we already have a hint that conflict in the personality may, by its effects on tissue fluids, be the cause of inviting and promoting this daemonic activity.

I believe that authentic cases of spontaneous disappearance of malignant growth, if rare, are known to exist. This would be explainable on these lines, as also the fact that carcinoma of the breast occurs more often on the left, the more unconscious side of the body. For in using dreams to understand the depths of the personality the psychotherapist becomes familiar with the fact that, in our right-handed civilization, the left side of the body and left-handed symbols represent something at a more unconscious level than similar objects represented on the right. Hence an assault on the soma engendered unconsciously in the psyche might well be expected to express itself in a left-sided manner.—I am, etc.,

Exeter.

E. JOYCE PARTRIDGE.

SIR,—Why, in the background of the admirable paper "Total War on Cancer" (July 20, p. 77), is there the suggestion of competition between the wars against different kinds of disease? Why, in fact, is there any hesitation in applying what we have learned of the finance of total war to the struggle for freedom from the ills to which our bodies are now heir?

Having returned from India but a couple of months ago, I cannot attempt to answer these questions, but a visit to Madanapalle in 1944 (to help a doctor with his mathematics) taught me a reply which may be worth stating now. As I

watched the fight against tuberculosis and realized how slow would be the returns from all the labour of operations and of nursing, it became evident that the costs of a total war against tuberculosis should fall as much as possible on future generations, which would receive most of the benefit. The implication of this is that the costs of such a fight should come from Government loans, and immediately, as the mobilization of resources and the training of personnel will be slower than for ordinary war, that no institution which is now doing good work in the fight should be frustrated for lack of funds.

To broaden the picture, the war against malaria is comparatively so simple as to be chiefly a matter of finance. In my own time in Bombay I have seen malaria cleared from the southern part of the island by routine expenditure from municipal budgets. Leprosy stands much on a par with tuberculosis as regards speed of returns. For cancer I get the impression that it is future generations that will benefit most from well-coordinated research, and so the cost of research into cancer might well come from loans—though this suggestion may seem unnecessary in England.

As regards education of the public to co-operate more effectively in reducing the mortality from cancer, has not investigation advanced so far that the main demand on the man in the street can be crystallized in slogans? So far as my education has gone I'd suggest the following: "Suspect cancer early without fear." "Cancer the most curable of diseases if taken quick." But such slogans would doubtless be the concern of local committees.—I am, etc.,

Wilson College, Bombay.

JOHN MACLEAN.

Trilene in General Practice

SIR,—Drs. A. Barratt and S. H. B. Platts are to be congratulated on their article on the use of trilene in general practice (July 6, p. 10). I am in full agreement with their main conclusions, but I feel that some points about administration warrant further discussion. The authors prefer a Clover's inhaler to the type of apparatus which delivers a fixed percentage of trilene, because patients vary in their response to, and need for, the anaesthetic. I have used Freeman's inhaler, which delivers a fixed percentage of trilene, in obstetrics in my practice for the past eighteen months, and find it excellent for producing analgesia. The point which I feel has been overlooked in the article of Drs. Barratt and Platts is that the amount of anaesthetic vapour inhaled by the patient is controlled not only by the inhaler used but by the rate and depth of the patient's respirations. Thus, I have found that towards the close of the second stage of labour, if the patient is told to breathe deeply and rapidly, with her finger on the small hole of the horizontal tube of the Freeman's inhaler to increase the percentage of trilene, one can obtain analgesia adequate for the delivery of a head in a normal case. Some patients go completely over in a minute or two with this procedure. The perineum can be stitched by repeating this process, but if anaesthesia is required I prefer to give trilene on an open mask, under which is run a constant stream of oxygen. Without the oxygen, tachypnoea and cyanosis may develop rapidly, and this makes me dubious about using the Clover's inhaler with the bag to produce anaesthesia. Perhaps the duration was short enough in the cases described to avoid these side-effects, but they can on occasion develop very rapidly at quite an early light stage of anaesthesia.—I am, etc.,

T. D. CULBERT.

Penicillin Therapy and Control in 21 Army Group

SIR,—May we be permitted to amplify the information given in the kindly review of *Penicillin Therapy and Control in 21 Army Group* in your leading article (July 13, p. 56)?

It is said that "the reader has to delve" because the various reports on the special investigation into the treatment of war wounds are not summarized. They are summarized and analysed in a complete article (pp. 143-156); as explained in this article, the technique of treatment approximated closely to the methods detailed in a separate publication (*Memorandum on Penicillin Therapy in 21 Army Group*), and to save space these were not repeated.

It is also stated that the question, "Is it possible to achieve good results by the simple and economical method of local application?", is not answered. The pioneer work of Florey and Cairns, confirmed later by Fraser, Jeffrey, Bentley, and others, supplied the answer to this question. We gave figures dealing with local penicillin both in prophylaxis (pp. 22-3) and therapy (pp. 144-5); it was shown (p. 144) that in a group of 2,359 patients whose wounds were sutured with the help of local penicillin only, excellent results were obtained. There is no doubt that local applications of penicillin powder are effective both in prophylaxis and therapy, but we wish to emphasize that, in our opinion, systemic administration in addition is essential to secure the maximum protection in those with complicated and lacerated wounds, especially if there are retained foreign materials.—We are, etc.,

A. E. PORRITT.

Of Secondary Importance

SIR,—I believe I am correct in stating that, according to a decision of the House of Lords, a professional man does not come under the law relating to master and servant as far as his employer is concerned. Mr. Bevan is reported to-day (July 24) to have said that "a good doctor may be a bad servant and if he fell short of what was required he would be liable to be removed." We do know now where we stand; the public may in future be deprived of the services of a good doctor if he does not entirely conform to the detailed requirements of civilian administrators. Clearly the well-being of patients is to be of secondary importance!—I am, etc.,

St. Mawes.

B. H. SHAW.

Book Reviewing

SIR,—I hesitate to reply to Mr. H. Osmond Clarke's letter of reproof (July 20, p. 102), lest he goes further and regards me as a general paretic. Only on one score has he any grounds for complaint against my pomposity, and that I think because he has misinterpreted the word "so" before "unsatisfactory" to mean a pedantic disparagement instead of simply "therefore" (June 1, p. 837).

The very worst person to review a book is one who knows the author intimately; he should no more do it than a surgeon should carry out a major operation upon his own child. To achieve objectivity in the space you allow your reviewers, a certain *ex cathedra* method is inevitable. Perusal of most medical reviews reveals this general tendency. Complete objectivity is assured by anonymity. We are your agents whom you select, presumably, because of our practical knowledge of a particular subject, our familiarity with the literature, and our insight into the interests of the very different groups of your readers. We take this duty seriously. Mr. Clarke has shown little reason for his objections. It is no part of a reviewer's function to parry an author's statement with statistical findings from the reviewer's experience. What I did say, and what Mr. Clarke is prepared to pass by, is that having agreed with older authorities that operations for cruciate ligament injury are rarely indicated, the author of the book had nevertheless found 17 patients upon whom to carry out an unproved procedure of his own invention, apart from the other operative measures which he describes. It is necessary that your readers know what are the merits of the author's operation. The statement that the results are dubious is merely a reflection of the author's report on the end results, and has nothing to do with the reviewer's judgment. What the reviewer does imply is that this matter was injected prematurely into the monograph, and should first have been displayed in the special literature after a proper presentation of cases before a medical audience qualified to discuss them.

"New" information was given about the function of the quadriceps muscle, and particularly the vastus medialis section. Unorthodox statements were made so dogmatically that, as there was no scientific anatomical or physiological support for these statements, I refused to accept them. These were examples of much else which suggested superficiality, over-

Self-Sterilising
LOCAL ANÆSTHETIC

$\frac{1}{2}$ %, 1% & 2% SOLUTIONS

FOR

MINOR & MAJOR SURGERY

Absolutely non-toxic in therapeutic doses and tolerated by even the most sensitive tissues, Novutox has the added advantage that it possesses a remarkable chemo-therapeutic action which promotes very rapid and clean healing of wounds.

Available in:

$\frac{1}{2}$ %, 1% and 2% Solutions: - - - **BOTTLES** of 2 ozs. and 20 ozs.
1% and 2% Solutions: **AMPOULES** 2 c.c. Boxes of 12 and 100.
CARTRIDGES of 2% Solution are available in boxes of 20 and 100.

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.00002 gm. epinephrine and 0.00002 gm. capryl hydro-cupreinotoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

THE INTRAVAGINAL TAMPON

in Menstrual Hygiene
minimizes the risk of infection

THE correct position of the internal tampon avoids contact with both anal and urethral sources of contamination. Tampax tampons are simply and hygienically inserted in correct proximity to the cervix by means of a disposable 'applicator' tube, only $\frac{1}{8}$ " in diameter. The function of the applicator in inserting the tampon at the upper end of the vaginal tract is of the greatest importance. It eliminates any handling of the highly-compressed soft surgical cotton, and ensures comfort and steady absorption. Tampax tampons are easily removed and disposed of, by means of a moisture-proof cord 'built into' the tampon in its first stage of manufacture, proof also against any risk of disintegration. The positive 'wick' action of the surgical cotton obviates any blocking of the flow.

Tampax may confidently be recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymenal aperture would cause difficulty in insertion and withdrawal.

tement, and premature publication, which one hopes will be a feature of British medical monographs. That is why criticism should be public. I appreciate that the author of the book in question had worked very hard, and so have any other young men who have seen a large amount of work under Service conditions, and who have dealt with large numbers of knee injuries. We would also like to have heard from them. There is still room for the publication of a work dealing with the derangements of the knee-joint arising from the experience of the recent war.

Finally, I am a practising surgeon, not yet senile, and sign myself,—

"ONE OF YOUR REVIEWERS."

Socialism and the Pay-bed

SIR,—I am surprised that you find three letters to support the contentions of Mr. J. B. Macalpine (June 22, p. 968). Mr. Macalpine apparently feels himself capable of "instructing the community in biological affairs." As a medical man, "trained in biology and in a position to understand genetics," I consider the letter a confused, unscientific piece of snobishness.

May I ask for a definition of the "desirable genes" which are in danger of being "lost and gone for ever"? May I ask for evidence that "social desirability and service" are hereditary? Is it the contention that acquired characteristics are also inherited? Or is the characteristic of "a fine level of intellectuality and sensibility" only "acquired" by "strenuous effort at perfection in the art of living"?

The contention of the whole-time medical officers of the Middlesex County Council is that privacy should be obtainable on medical grounds. Surely they would agree that "mental sufferings," which Mr. Macalpine so readily attributes to his "highest types," would indeed be legitimate grounds for isolation.

In what way can it be said that the abolition of the pay-bed is the "stamping out of desirables"? There seems to me no connexion whatsoever between this bigoted approach to the principles of genetics and Socialism and the subject of the pay-bed. To make special medical provision for these "superiors" because of their ability to pay is to try to perpetuate a sense of values only appropriate to the Victorian age. I am glad that, in common with the medical officers of the Middlesex County Council, I have never possessed this "sense of value."—I am, etc.,

Hessle.

IAN C. GILLILAND.

A New Decalogue

SIR,—*Magna est veritas et praevalabit.* The tag sounds more impressive in Latin, which serves to accentuate the complete falsity of the sentiment. The wishful thinking that inspires it is, in fact, little short of pathetic in the light of experience. The subject is brought into relief again in the new book on Morell Mackenzie reviewed in your columns on June 8 (p. 880). This is, perhaps, not the place to go into a detailed consideration of the pros and cons of this case. But one comment, I think, is justified, if not demanded, and that is the nauseating unscrupulousness with which the situation was manipulated and the facts distorted from political motives. Nausea is the appropriate reaction to this little cameo of history.

Can we draw any reassuring lesson from this episode? Can we say that things are better at the present time? Have we developed in the interval a more scrupulous respect for facts and accuracy of statement? Making every allowance for its "many-sidedness," it would seem that even to-day, when the muddled hand of politics touches science, truth will suffer. That it inevitably will prevail is a dangerously misleading notion. Rather, the tag should be altered to read that truth is a fragile flower that every man (even the politician) must, on his conscience, cherish. I should like to see a re-statement of the relevant Commandment in exceedingly intimidating terms beginning: "Let no man tamper with the Truth." A modern Moses in a new decalogue would, I am sure, feel to-day that first place should be given to this injunction. Most of the others are of little consequence in comparison.—I am, etc.,

London, W.I.

FREDERICK DILLON.

Obituary

R. E. ROBERTS, M.D., F.R.C.P., F.F.R.

By the sudden death of Dr. R. E. Roberts we have lost a man of outstanding ability, a loyal colleague, and one whose personality endeared him to all with whom he came in contact. It is not only for his scientific and administrative gifts that he will be missed, but also for that sincere genial manner and human sympathy, coupled with an urge to help others, that enabled him to see and understand the other man's point of view. These gifts often helped him to compose the differences that are inevitable in human affairs. His willingness to undertake thankless and uncongenial tasks brought burdens of worry that did much to undermine his health, so much so that during the last three years he had had to withdraw from many of his activities, particularly in London.

Born in 1890, educated at the Birkenhead School and at Liverpool University, he took his B.Sc. in 1908. He then turned to medicine and qualified M.B., Ch.B. in 1914, having gained the Junior Lyon Jones Scholarship, the Holt Medal in Physiology, and the Derby Exhibition in Surgery. On the outbreak of war he at once joined the Forces and served from 1914-18 in the R.A.M.C., chiefly in India, being mentioned in despatches. Returning to Liverpool he took his D.P.H. in 1919, but very soon turned to radiology and was one of the first small group who took the Liverpool D.M.R.E., which had just been inaugurated at the instance of Dr. Thurstan Holland. Entering into partnership with Dr. J. H. Mather, and later with Dr. Holland, there followed twenty years of very active work in which Roberts produced a series of important contributions to the radiology of bones and to the study of pelvimetry. For the most part these were published in the *British Journal of Radiology*. He also contributed a section to the standard *Textbook of X-ray Diagnosis*, edited by Shanks, Kerley, and Twining.

Thurstan Holland was the dominating figure in radiology for many years, but as he became less active Roberts gradually took his place, succeeding him as Honorary Radiologist at the Liverpool Royal Infirmary and also in teaching for the Liverpool Diploma in Radiology. In the affairs of the Liverpool Medical Institute he took an active part, and had held the offices of Vice-President and General Secretary. In London he upheld for Liverpool the prestige that had been established by Thurstan Holland, taking over the leading offices in the radiological societies. He was President of the Section of Radiology of the Royal Society of Medicine, 1937-8, President of the Faculty of Radiologists, 1939-40, and Vice-President of the British Institute of Radiology, 1938-9. He was nominated President of the Institute in 1943, but had to withdraw owing to illness. He examined for the Fellowship of the Faculty of Radiologists, and for the diplomas in radiology of the Conjoint Board, and of the London and Liverpool Universities. During the war the Liverpool diploma was suspended, but it is typical of Roberts's views on the importance of radiology and the necessity for thorough training that at his instance the diploma has been replaced by a degree in radiology, but, alas, he will not be there to direct this course when it is due to start next September. With a view to increasing teaching facilities in this course he had just resigned from the Liverpool Royal Infirmary to take up a similar appointment at the Liverpool Southern Hospital.

During the war Roberts was one of the regional advisers in radiology for the E.M.S., and he also served as Honorary Consultant Radiologist to the Army at home, in which capacity he examined all the officers who were trained in radiology at Millbank. In appreciation of all his services he was recently elected to the Fellowship of the Royal College of Physicians.

The selfless devotion with which Roberts gave of his time and energy was an inspiration to many of his colleagues, who appreciated not only all that he did, but also the willing co-operation of his partner, Dr. J. H. Mather, who made his frequent absences from Liverpool possible. Diagnostic radiology suffers a severe blow in the premature death of this devoted worker whose loss will be felt for many years not

only in Liverpool but in the radiological counsels of the country. To his wife and two daughters we extend our sympathy.

A. E. B.

The sudden death of Dr. Robert Edward Roberts, at the age of 57, came as an unexpected shock to a wide circle of friends in the profession and particularly in the radiological world. It further depletes the distinguished group of provincial radiologists who did so much to build the reputation of British radiology between the two world wars. In the 'thirties a Lancashire triumvirate—Roberts from Liverpool, and R. S. Paterson and Twining from Manchester—took a commanding part in the radiological activities of the country, and on the death of both the Manchester radiologists in 1938 Roberts was looked upon as the leader of the diagnostic radiologists of the North. The claims of a busy hospital and consulting career were not enough to satisfy his energy and ability, and it was not long before he began to interest himself in the scientific, academic, and administrative aspects of his specialty. He published a number of important papers, and his early work on x-ray investigations in obstetrics and gynaecology soon established him as an authority on the subject.

Robin Roberts had an endearing personality which combined a scientific outlook, clinical acumen, and charm of manner in a way that won him success in whatever he attempted, and the respect and affection of all who knew him. More than any other quality it is perhaps his personal and social charm that will linger longest in the memory of his friends. A week before he died, the writer found him full of *joie de vivre*, and enthusiastic for the future. The end was brief and unexpected, as he would have wished, and British medicine is the poorer for his passing.

S. C. S.

Universities and Colleges

UNIVERSITY OF LONDON

At a meeting of the Senate, held on July 24, the following appointments were made:

Neil Hamilton Fairley, C.B.E., M.D., D.Sc., F.R.S., F.R.C.P., to the Wellcome Chair of Tropical Medicine tenable at the London School of Hygiene and Tropical Medicine, from Oct. 1; George Macdonald, M.D., D.T.M., D.P.H., to the University Chair of Tropical Hygiene tenable at the London School of Hygiene and Tropical Medicine, from Oct. 1; Francis Cyril Oliphant Valentine, M.R.C.P., to the University Readership in Chemotherapy tenable at the London Hospital, from Oct. 1.

The title of Professor of Morbid Anatomy and Histology in the University has been conferred on Robert Wilfred Scarff, M.B., B.S., in respect of the post held by him at the Middlesex Hospital Medical School.

The title of Prof. Emeritus of Helminthology in the University has been conferred on Prof. R. T. Leiper, C.M.G., D.Sc., M.D., F.R.S., F.R.C.P., who retires in Sept. from the William Julien Courtauld Chair of Helminthology at the London School of Hygiene and Tropical Medicine, which he has held since 1917.

The title of Professor Emeritus of Experimental Pathology in the University has been conferred on Prof. E. L. Kennaway, M.D., D.Sc., F.R.S., F.R.C.P., who retires in Sept. from the Chair of Experimental Pathology at the Chester Beatty Research Institute of the Royal Cancer Hospital, which he has held since 1931.

UNIVERSITY OF MANCHESTER

Prof. Henry Stanley Raper, C.B.E., D.Sc., M.B., Ch.B., F.R.S., F.R.C.P., who has held the Chair of Physiology in the University since 1923, has accepted an invitation to become full-time Dean of the Medical School and Professor of Chemical Physiology, from Sept. 29.

The Council has appointed Walter Schlapp, Ph.D., M.B., Ch.B., at present Reader in Experimental Physiology and Assistant Director of the Physiological Laboratories, as Brackenbury Professor of Physiology and Director of the Laboratories from Sept. 29, in succession to Prof. Raper.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the College held on July 25, with Mr. James M. Graham, President, in the chair, the following, having passed the requisite examinations, were admitted Fellows:

R. D. I. Beggs, H. W. Gallagher, G. C. Gordon, D. B. Handelman, R. W. B. Holland, C. McT. Hopkins, P. Jardine, J. P. Lane, T. J. McCormac, M. McLeerie, A. McL. Millar, G. H. Moore, J. F. Paxton, H. H. Pearson, N. A. Punt, S. Sacks, D. G. Simpson, W. M. Van Essen.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council held on July 27, with the President, Mr. Eardley Holland, in the chair, Mr. William Gilliatt, C.V.O., M.D., M.S., F.R.C.S., F.R.C.O.G., was elected President to take office in September next. Robert Marshall Allan, M.D., F.R.A.C.S., Hon.F.A.C.S., F.R.C.O.G., and Sir William Fletcher Shaw, M.D., F.R.C.P., Hon.F.A.C.S., F.R.C.O.G., were elected vice-presidents.

The following candidates were elected to the Membership:

H. R. Arthur, S. J. Barr, B. E. Blair, Catherine I. Blyth, Joyce M. Burt, H. Burton, G. B. W. Fisher, B. G. Halder, R. L. Hartley, D. Jefferiss, Iola I. T. Jones, L. W. Lauste, Elizabeth McCallum, Margaret Orford, H. C. Perry, Dwifendra L. Poddar, Esther M. Pollock, J. E. Scott-Carmichael, W. R. Sloan, R. A. R. Taylor, E. W. L. Thompson, T. G. E. White.

Medical Notes in Parliament

The Royal Assent to the National Insurance Act was given on Aug. 1.

Parliament will reassemble on Oct. 8. The Second Reading of the National Health Service Bill is set down for that day in the House of Lords.

Hospital Finance in the Interim

On July 25 Major LEGGE-BOURKE invited Mr. Bevan to say how many intimations he had received from hospitals that they were having to dispose of their assets in default of voluntary contributions since the announcement of the introduction of a health service scheme. Mr. BEVAN replied that he had been approached by a few hospitals about their general position, but was not aware of any case of the kind described by Major Legge-Bourke.

Mass Radiography Progress

Mr. Bevan was asked on July 25 if his advisers had come to any decision as to the periods at which mass photographs of the population should be made to diagnose early cases of tuberculosis. Mr. BEVAN said there could be no standard rule about frequency of examination. Regular survey of the same groups was obviously desirable, but present resources—which were steadily increasing—still kept short of that ideal. Replying to a further question Mr. Bevan stated that the number of civilians examined by mass radiography in England and Wales up to Dec. 31, 1945, was approximately 797,000, of whom 2,900 were diagnosed as suffering from active tuberculous conditions. Of those requiring institutional treatment 830 had been admitted to such treatment up to Dec. 31 last, and admissions since then would have substantially increased this number.

Cancer

Mr. WATKINS on July 25 asked the Minister of Health to consider setting up an independent commission to inquire into the progress, if any, made by the various uses of radium in the cure of cancer.

Mr. BEVAN answered that he did not consider such a commission to be necessary, since the progress of cancer research and treatment was kept continuously under review by the bodies concerned.

Death rates per 1,000 population in England and Wales from cancer, 1936-45, were given by Mr. Bevan on July 25 as follows:

1936	1.575
1937	1.583
1938	1.616
1939	1.628
1940	1.723
1941	1.780
1942	1.834
1943	1.899
1944	1.897
1945	1.933

(provisional)

(The rates for the years 1939 to 1945 relate to civilians only.)

Although these rates showed an increase, Mr. BEVAN's information was that earlier diagnosis was resulting in reduced mortality, which was concealed by the simultaneous increase in ascertainment through better facilities for diagnosis and treatment.

Mental Defectives in Institutions

Mr. BEVAN on July 25 regretted that figures of the number of mental defectives now in institutions were not available, but added that the number on Jan. 1, 1946, was 52,788. This, he said, was approximately 20% of the estimated total number of

fectives in the country, many of whom, however, did not require institutional care. He had authorized the Board of Control to consider plans for the provision of additional accommodation for low-grade and tuberculous patients, whose care in ordinary homes imposed great hardship upon parents.

Nutritional Standards in School-children

On July 23 Mr. WESTWOOD told Mr. Willis that all education authorities in Scotland had been advised that the classification "bad nutrition" should be used to cover only those children who, in the opinion of the medical officer, were suffering in a serious degree in consequence of bad or insufficient feeding. Nutrition standards were not capable of exact statistical measurement, but the findings of the school medical officers served their main purpose of drawing attention to those children who appeared to require medical supervision and, if necessary, treatment.

Prevention of Blindness in the Colonies

Mr. GEORGE HALL told Mr. E. Edwards on July 24 that the Empire and Colonial Development Subcommittee of the National Institute for the Blind, under the chairmanship of Mr. Bernard Reilly, had suggested a joint tour of various colonies by representatives of the Institute and of the Colonial Office to report on methods of preventing blindness and of providing welfare services for the blind. This tour had just begun. It was proposed to visit most of the East and West African Colonies, Cyprus, Palestine, and Aden.

Rehabilitation of War Casualties

In a reply on Aug. 1 Mr. WILFRED PALING said it could not be claimed that cases of serious spinal injury could be restored to a condition approaching normality in the sense of full mobility, but modern methods of treatment substantially reduced the mortality rate in these cases and enabled the majority of the men to get about in self-propelled or motor-propelled chairs instead of being permanently confined to bed. He estimated that, on the completion of treatment and, where necessary, training, about 60% would be able to undertake remunerative employment. Artificial limbs had been supplied in about 15,000 cases since 1939, of which 12,000 were war-disabled cases. Practically all of the persons concerned had been fit to take up remunerative employment or undergo training for employment.

Mr. Paling further explained that the Plastic Surgery and Jaw Unit at Roehampton Hospital was enlarged in 1939 to deal with Service cases and air-raid casualties. Considerable advances had been made, the most important of which were the insertion of special material, known as tantalum, for the restoration of facial contours, the fixation of skin grafts by specialized methods, the making of skin flaps for amputation flaps, the treatment of chronic disease of bone, and the development of a highly specialized physiotherapy service. Co-operation with the orthopaedic unit and dental department had been developed on a large scale, and an excellent photographic department capable of producing technical cinefilms had been built up. As regards research, he made special mention of the investigations into the conditions influencing the healing of war wounds and the development of scar tissue. Mr. Paling expressed appreciation of the invaluable work done by the medical and dental officers, nurses, and other staff in the care of the patients in this hospital.

Diphtheria Notifications and Immunization

Mr. BEVAN furnished on Aug. 1 figures relating to diphtheria notifications between January, 1940, and June, 1945. He explained that the figures for, and subsequent to, 1944, reflected corrections made at infectious diseases hospitals; material for in exact comparison with the years 1940 to 1943 was not available. The details are:

Year	Original Notifications	Corrected Notifications
1940	47,165	46,280
1941	51,298	50,804
1942	42,580	41,404
1943	36,017	34,662
1944	29,949	23,199
1945 (January-June)	11,993	8,531

On Aug. 1 Mr. PETER FREEMAN asked Mr. Bevan to ensure that in all future advertisements recommending the practice of immunization a statement was added that 19,040 children contracted diphtheria after submitting to this operation and of these 142 died in the last five years, "in order that the public may have the full facts concerning immunization."

Mr. BEVAN refused the proposal and added that he could not agree that this would be giving the public "the full facts."

He went on: "Obviously you cannot guarantee absolute immunity in every case; but the most striking facts are that the chance of a child's death from diphtheria is twenty-six times greater if it is not immunized and that deaths from diphtheria have been reduced to about a quarter of the pre-war-yearly average."

Streptomycin

Mr. THOMAS BROOKS inquired on Aug. 1 what steps were being taken to import supplies of streptomycin from the U.S.A.; and what efforts were being made to manufacture it in this country. Mr. BEVAN said American production of streptomycin was too small to permit export to this country. Arrangements were being made with the Ministry of Supply and the Medical Research Council to set on foot the manufacture in Great Britain of sufficient streptomycin for adequate clinical trials.

Polish Doctors in Britain.—Sir JOCELYN LUCAS asked on July 25 how many Polish military doctors, being repatriated with General Anders' army, would be allowed to practise in this country other than with the Resettlement Corps. Mr. BEVAN said he was considering this matter, but was not yet in a position to give the detailed information asked.

Malaria in British Troops in Japan.—On July 23 Mr. LAWSON stated the incidence of malaria in Japan as a whole, for British troops, was very small. In the fortnight ending May 31, 1946, three cases were reported, and in the fortnight ending June 14, 1946, one case. All the usual anti-malarial precautions, and certain special measures which included spraying with D.D.T. and the arsenical compound (Paris Green), were being taken.

Medical News

Mr. John Pringle, Deputy Editor of *The Listener*, has been appointed Press Officer to the British Medical Association. Mr. Pringle was formerly responsible for "The World Goes By" broadcast feature, and was a member of the editorial staff of *The Manchester Guardian*.

The residential summer school on "Healthy Living" at the University of St. Andrews, arranged by the Scottish Council for Health Education, opened on Aug. 3 and continues until Aug. 17. Subjects for discussion during the second week include the quest for pure food (Aug. 12); mental affliction (Aug. 13); adolescence and senescence, venereal disease (Aug. 14); homeostasis, tuberculosis (Aug. 15); and the case for eugenics (Aug. 16). Films on various subjects will be shown each evening from Monday to Friday at 8 p.m.

The County Borough Group of the Society of Medical Officers of Health held its Annual Meeting from July 19-22 at Eastbourne, under the presidency of Dr. R. H. H. JOLLY. Among the addresses given at the conference was one by Dr. SCOTT WILLIAMSON on the work of the Peckham Pioneer Health Centre from its foundation. Dr. F. FENTON, the Medical Officer of Health of Eastbourne, in a paper on "The Care of Homeless Children" stressed the need for co-ordination of their care through the person of the medical officer of health. Prof. J. M. MACKINTOSH outlined his ideas on the training of medical administrators and on the scope of their activities. Dr. W. S. WALTON, the newly appointed Medical Officer of Health for Newcastle-upon-Tyne, was elected president of the Group for the coming year. The secretary is Dr. J. GREENWOOD WILSON.

Prof. P. F. Armand-Delille, a member of the French Academy of Medicine, is on a visit to this country under the auspices of the British Council to gather information on British social services. He is visiting various organizations in London, Birmingham, and some rural areas, under the guidance of the National Council of Social Service.

The Medical Research Council have made arrangements with King's College Hospital Medical School, London, for the establishment of a dental research unit there under the direction of Dr. J. D. King, a member of the scientific staff of the Council.

Certain admirers of the work and career of the late French scientist Prof. Antoine Béchamp hope to hold a small dinner in his honour on Oct. 16, the anniversary of the date of his birth in 1916. If any who might like to attend will write to Mrs. L. S. Caffyn, 31 Chelsea Gardens, London, S.W.1, further particulars will be supplied.

There was some discussion at the Annual Representative Meeting (Supplement, Aug. 3, p. 38) on the need for operating gowns, and the coupons wherewith to obtain them. The Board of Trade has recently had under consideration the possibility of the supply of coupon-equivalent certificates to doctors in private practice for whom white operating gowns are essential. It has now been agreed that any practitioner who needs gowns in his private practice for obstet-

rical work, treatment of venereal diseases, operations, or necropsies, shall be entitled to obtain six surgeons' operating gowns. Private practitioners in England and Wales who require gowns for these purposes should apply, stating particulars, to the Ministry of Health, Whitehall, London, S.W.1. Doctors in Scotland should write to the Department of Health for Scotland, St. Andrew's House, Edinburgh. Practitioners in Northern Ireland should apply to the British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, enclosing a stamped addressed envelope.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* a rise occurred in the notifications of whooping-cough 204, scarlet fever 91, and cerebrospinal fever 16; decreases were recorded for measles 198 and diphtheria 30. Whooping-cough notifications were the largest for over two years. During the week there were small increases in many areas and the largest variations were a rise in Staffordshire 35 and a fall in Lancashire 63.

Scarlet fever increased for the whole country; the largest of the local changes was a decrease in Lancashire of 32. Large falls in the notifications of measles were recorded in Lancashire 213 and London 138, while the largest rises were Staffordshire 56 and Kent 44. A further decline from the record low level of diphtheria was recorded; the chief fluctuations were falls in Lancashire 23 and Yorkshire West Riding 10, with an increase in Warwickshire 10. Dysentery remained at the low level of the preceding week, and the only large returns were those of Yorkshire West Riding 10 (Bradford C.B. 9), and the Port Health District of Southampton 8.

In *Scotland* there were only small variations in the incidence of infectious diseases, except for measles, which declined by 66. The notifications of diphtheria fell by 4 for the whole country, but a rise of 10 was recorded in Glasgow.

In *Eire* notifications of diarrhoea and enteritis fell by 10 to 54, and cases of diphtheria decreased by 9. A rise occurred for measles 16, whooping-cough 10, and scarlet fever 8.

In *Northern Ireland* whooping-cough rose by 10 cases and diphtheria by 5, while a fall of 8 was recorded for scarlet fever.

Quarterly Report for England and Wales

The birth rate during the first quarter of the year was 17.2 per 1,000, which was 1.5 above the average of the five preceding March quarters. Stillbirths formed 2.8% of the total births registered. Infant mortality was 55 per 1,000 live births and was 14 below the average of the ten preceding first quarters. The general death rate was 14.8 per 1,000 compared with 15.7 for the average of the five preceding March quarters.

Birth Rate in June Quarter

The Registrar General for England and Wales has stated that 203,797 live births were registered during the June quarter of this year. This number is equivalent to a birth rate of 19.2 and is the highest recorded in any June quarter since that of 1925.

Statistical Review

The publication of the Registrar General's annual statistical reviews, suspended during the war, is now being resumed. So at the latest statistics shall be available again as soon as possible, the Registrar General is now preparing the Review for 5, which will contain both medical and civil tables, and it is hoped to publish these later in the year. This will then bring the series up to date except for the reviews for the war years 1942-3-4, which will be issued separately as soon as possible.

Quarterly Return for Northern Ireland

The birth rate during the first quarter of the year was 21.9 per 1,000, which was the same as the average of the five preceding quarters. The infant mortality was 64 per 1,000 registered births, compared with 95 in the corresponding quarter of the previous year and 91 as an average for the five preceding March quarters. Maternal mortality was 3.3 per 1,000 births, the same as the five-year average. The general death rate was 16.4 per 1,000 and was 0.1 above the average for the five first quarters. The number of deaths from pulmonary tuberculosis was 247 and from other forms of tuberculosis 64, the averages of the first quarters 1941-45 being 255 and 79 respectively.

Week Ending July 27

The notifications of infectious diseases during the week in England and Wales included: scarlet fever 994, whooping-cough 2,468, diphtheria 308, measles 3,741, acute pneumonia 363, cerebrospinal fever 41, dysentery 90, acute poliomyelitis 18, paratyphoid 14, typhoid 8.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 20.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

ANY QUESTIONS?

Common Cold and Duodenal Ulcer

Q.—*Why does a common cold aggravate the symptoms of duodenal ulcer?*

A.—It is a well-established fact that catarrhal infections, including the common cold, will bring about a relapse of symptoms in a number of alimentary conditions, notably duodenal ulcer. In this respect it is second only to emotional stress as a cause of ulcer recurrence. It is difficult to say exactly how or why this comes about. The ulcer base has been shown, particularly by French observers, to be an infective area, and various organisms, notably enterococci and non-haemolytic streptococci, have been obtained from it on culture. It seems reasonable to suppose that this area becomes sensitized and re-activated by the organism of the catarrhal infection, or perhaps by the general tissue response to the accompanying low-grade fever. Rosenow's theory of the elective affinity of streptococci, notably those found in oral sepsis or certain damaged tissues, especially peptic ulcer, may be cited as a possible mechanism, though his work has not received confirmation in this country. The practical point to remember is that in all schemes directed towards the prevention of ulcer recurrence emphasis must be laid on the need for drastic modifications in the diet and a short period of rest in bed in the presence of these infections.

Urobilinogen Excretion in Infective Hepatitis

Q.—*The presence of excess of urobilinogen in the urine is often used as an index of liver damage, particularly in the early diagnosis of infective hepatitis. What is the rationale of the test?*

A.—Urobilinogen is formed in the bowel by bacterial action (reduction) on bilirubin. A proportion is reabsorbed into the blood stream and re-excreted by the liver in the bile. If the liver cannot deal with all the urobilinogen presented to it, increased amounts will appear in the urine. This function of re-excretion by the liver is one which tends to fail early in many types of hepatic damage, especially in infective hepatitis, so that urobilinuria is often an early and valuable indication of liver dysfunction. Either the presence or absence of the pigment in the urine must, however, be cautiously interpreted in cases of frank jaundice (where bilirubin, and therefore urobilinogen, may be absent from the bowel) and if excessive haemolysis is occurring, when the excretory function may be so overloaded that very slight hepatic impairment is sufficient to allow urobilinuria to appear. Incidentally, urobilin and urobilinogen have the same significance in this connexion, the distinction being merely one of technique.

Dupuytren's Contracture

Q.—*What are the late results of the operative treatment of Dupuytren's contracture?*

A.—The results are very good if the operation is done at the correct time and in the approved manner. The correct time for operation is before the ligaments and joints of the finger become secondarily affected. The approved method is to remove all the contracted palmar fascia through an incision not in the line of an affected finger but so planned that it runs as nearly parallel as possible to the creases of the palm. If

the skin of the palm is attached to the contracted fascia it must also be excised and a graft of whole skin taken to make good the gap in the palm. A pedicle-graft may be utilized.

Artificial Blondes

Q.—*A patient of mine is in the habit of bleaching her hair periodically with a mixture of hydrogen peroxide (20 vol.) and ammonia (about 2 parts to 1 part). She has been informed by a hairdresser that this will eventually destroy the hair roots. Is this true? If not, is there any danger?*

A.—It has been suggested that the different colouring of the hair is due to differences in the keratin and not to different kinds of colouring matter. Whether this be accepted or not, it is evident that to change dark hair to the fashionable blonde calls for drastic treatment, such as that described above. The effect is to make the hair lighter in colour, but harsh in texture and liable to split, which can hardly be beneficial. The popular description of the roots being darker refers to the darker texture and colour of the hair near the scalp, which may be due to the natural growth of the hair or to technical causes. The true roots or papillae are situated in the skin and are unlikely to be affected by external applications.

Idiopathic Epilepsy

Q.—*Can idiopathic epilepsy be due to a very heavy strain—e.g., carrying or pulling or pushing a very heavy weight?*

A.—There is no evidence that physical stress of the sort mentioned could bring about an idiopathic epilepsy. According to the modern conception this disease is a constitutional and largely inherited paroxysmal disorder of cerebral activity.

Significance of Renal Glycosuria

Q.—*What is the true clinical significance of renal glycosuria? Does the condition ever lead to true diabetes, and should a patient with renal glycosuria be accepted for life insurance at ordinary rates?*

A.—Provided that the sugar tolerance curve is within normal limits, glycosuria is not of any significance. The health remains good and the patient is neither more nor less likely than anyone else to develop diabetes later on in life. He should be accepted for life insurance at ordinary rates. The amount of sugar lost in the urine is usually small—5 or 10 g. a day, though as much as 30 g. may be excreted in the day. This is a very small amount and the glycogen in the liver and muscles can easily be maintained by an adequate diet.

A very low threshold occasionally occurs in some patients with true diabetes mellitus. The control of the diabetes is then much more difficult, as qualitative urine tests are useless and the blood sugar must be estimated more frequently. Sometimes very large amounts of sugar are excreted although the blood sugar is not much raised. In these circumstances the total sugar excreted in the urine in the twenty-four hours must be estimated, and if the patient is excreting, say, 100 g. a day the carbohydrate content of the diet must be raised to 200–300 g. in the day, with a corresponding increase of insulin to make certain that the body, and the liver especially, has enough glycogen. If the total daily output of sugar is estimated at intervals, and the insulin and diet are adjusted according to the results, these patients keep very well.

Amoebic Dysentery

Q.—*(1) How should I treat a mild case of amoebic dysentery? (2) Can chiniofon be given by mouth, and which preparation do you recommend? (3) Is rest in bed necessary for a mild case?*

A.—1.—In a mild case of amoebic dysentery it is not necessarily easier to eradicate the infection, nor is the disease necessarily less prone to relapse than a more severe case. Consequently treatment should be thorough in all cases. A favoured standard treatment consists of a twelve-day course of emetine bismuth iodide 3 gr. (0.2 g.), in a loosely packed capsule each night, and preceded half an hour before by phenobarbitone 1 gr. (65 mg.). Each morning of this course the patient is also given a retention enema of 200 ml. of 2% solution of chiniofon, which should be retained for four or five hours, and which is

preceded by a bowel washout of 2% sodium bicarbonate solution. This twelve-day course is then followed by treatment with an arsenical drug, for example carbarsone 0.25 g. by mouth, morning and evening, for a further ten days.

2.—Chiniofon may be given by mouth. Chiniofon is the *Pharmacopoeia* name for a standard iodo-hydroxyquinoline compound. This product is marketed by different firms under different names, and the product of any reputable firm should be equal in its therapeutic effect to that of any other reputable firm. Administered by mouth in amoebic dysentery it appears to produce less satisfactory results than does the combined treatment outlined above.

3.—During the first fortnight of the treatment recommended in para. 1, the patient should be kept in bed.

Cholecystitis and Duodenitis

Q.—How can one differentiate between mild cholecystitis and duodenitis and duodenal ulcer without x-ray examination?

A.—It is difficult and at times impossible to distinguish between these three conditions in the absence of radiology, and even this may fail to do so. Generally speaking, the symptoms of cholecystitis lack the periodicity of ulcer dyspepsia and are more likely to be associated with excessive flatulence and with such toxic manifestations as furring of the tongue, anorexia, and even vomiting. Tenderness, if present, will usually be confined to the gall-bladder, Murphy's sign may be present, and there may be local areas of tenderness to the right of the sixth dorsal spine (Ryle) or the twelfth dorsal spine (Boas).

It would be worth while trying the effects of a course of sulphadiazine or sulphamethazine, which are excreted into the gall-bladder in high concentration. More empirically, a course of hexamine, 20 gr. (1.3 g.), with a full dose of alkali to prevent gastric irritation, has been credited with satisfactory results in cholecystitis. Duodenitis is a pathological rather than a clinical condition and its symptoms are probably indistinguishable from those of duodenal ulcer.

Sex-determination

Q.—Is there any recent new knowledge of sex-determination? Has the theory of Dawson (1921) any foundation?

A.—The basis of sex-determination in man, elucidated many years ago, has required no modification. The female somatic cell contains two x-chromosomes, hence the ovum contains one. The male somatic cell contains an x- and a y-chromosome, hence approximately half the sperm contain an x and half contain a y. The sex of the future individual is determined at the moment of conception and depends simply on which kind of sperm happens to fertilize the egg. The sex ratio does depart somewhat from equality, however, and it has been shown, for example, that the younger the mother the more likely she is to have a boy. There are also indications that the tendency to

duce an excess of boys, or vice versa, may be inherited. Therefore it is clear that there are influences that make it on rather less or rather more likely that it will be an x-bearing sperm that fertilizes the ovum. These are slight tendencies, however, only detectable in the averages of very large numbers. From the point of view of any individual parent the chance is pretty close to 50-50.

Dawson's theory, perhaps the best known of several of the same type, postulates that one ovary produces eggs destined to give rise to females and that the other gives male-producing eggs, and that the ovaries function alternately at successive ovulations. There is no scientific basis for these theories.

Psychological Impotence after Long Separation

Q.—I have been consulted lately by several men, all about the age of 45, who after service abroad for some three or more years return home to their wives to find themselves completely, or almost completely, impotent. Instead of happy reunion after so many years apart, the marriage is in danger. I am convinced that this impotence is psychological, but what is the explanation and what advice can I give them?

A.—The problem here presented involves the whole personality and not merely the sex functions. It is a problem of readjustment and psychological rehabilitation. The war and

absence change the relationship between husband and wife, a change in which both are affected. For one thing, wives have had to be more independent and therefore self-sufficient; they do not need their husbands so much as before, and therefore to the husband have become different persons. On the other hand, the husband has either developed a much broader outlook on life, or he may return war weary and desire more affection from the wife, whose independence makes her less willing to give it. His war weariness may go to the extent of developing a "mother" complex towards his own wife, which in itself is sufficient to produce an inhibition of sex. In other cases a different mechanism is found, namely, that absence has made each idealize the other, especially the soldier who idealizes both his wife and home. After the first rapture the reunion may be in the nature of an anticlimax: each thinks the other has "changed," which indeed is true, but the change is often in contrast to the ideal. These problems of rehabilitation of returned Servicemen have been studied by Dr. A. T. Wilson and embodied in a paper, "The Service Man comes Home." Among more normal reasons is the possibility that the wife may have made other attachments, though not necessarily of a sexual nature, to some other man, and being now more conscious of other men has less regard for her returning husband. There is also the obvious possibility that in the Middle East the husband may have met some younger and perhaps more exotic girl with fewer inhibitions, and it is an anticlimax to return to the more mature and stable, if not drab, circumstances of life. The middle-age factor is important: the wife, though still attractive, may not make the same glamorous appeal.

During their enforced separation both husband and wife have each taken a lot of trouble to adapt themselves to being without the other. Having once established this new set-up in the personality, it is difficult for them to readapt themselves to their partners. Time, trouble, and patience are required to re-establish their relations. These relations will not be the same as previously, for even in ordinary marriage we need to readjust ourselves differently at each phase of life. But with readjustment of such personal relations, the sexual life will re-establish itself as an expression of affection.

In many cases we find that war service and separation have only served to bring to light an incompatibility of temperament or disposition which was already present before the break, so that the break becomes a welcome relief, and there is reluctance to resume former relations. A readjustment in such circumstances is very difficult. It will be observed that we cannot regard the sex functions in isolation, but need to regard the reactions of the whole personality, which requires to be thoroughly investigated.

LETTERS, NOTES, ETC.

Acid Treatment of Tetany

"MGANGA" writes: With reference to Dr. Marjorie Bourdillon's note (June 8, p. 902), I had an exactly similar condition in a male patient very recently. The onset was sudden and occurred after three days of a febrile illness, at first undiagnosed but which later was clearly typhus. Sweating and vomiting had been prominent symptoms just before the attack started. I obtained just as dramatic a cessation by administering two tumblerfuls of slightly hypertonic saline—by mouth, of course. I suggest that in my case and Dr. Marjorie Bourdillon's personal experience loss of chlorides due to sweating in the febrile attack occurring in a subject already low in salt was the real cause of the attack. In my case the patient was a railway employee occupied out of doors. He normally sweated freely at his work and was accustomed to drink large quantities of water. While taking food he just managed to maintain a chloride balance. Three days of fever, fluids, vomiting, and no food upset this, and the attack was the result. In Dr. Bourdillon's case lactation and malaria would have the same effect. In passing, I have succeeded in re-establishing lactation in a case where this was beginning to fail after three months, merely by prescribing a daily tumblerful of normal saline.

Health Service Bill

Dr. LESLIE HARTLEY (Camberley) writes: Mr. Douglas Houghton explained on the wireless in fifteen short minutes how many B.U.s were necessary to buy a small loaf in this country, twelve months after total victory. I hope some similar speaker will give a talk on the National Health Service when it comes in, so that fond parents may be able to decide whether to spend their P.U.s on little Willie's tonsils and adenoids or on another bottle of liquid paraffin for granny.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 10 1946

PROCEEDINGS OF COUNCIL

Tuesday, July 23

A meeting of the Council of the Association was held on Tuesday, July 23, immediately preceding the Annual Representative Meeting. Dr. H. Guy Dain was in the chair.

The Chairman said that during the previous week the death had occurred of one of the great figures in the Association. Sir Ernest Kaye Le Fleming had been associated for more than twenty years with the Association's central work in one capacity or another. He was Chairman of the Representative Body, 1931-4, and Chairman of Council, 1934-9. He was a most worthy successor in the line of extraordinarily able Chairmen who had immediately preceded him—J. A. Macdonald, Robert Bolam, and Henry Brackenbury—a line of which any organization might be proud. The members of Council expressed their sense of grief and loss and their sympathy with Lady Le Fleming and her family by standing in silence.

It was decided that a special Council meeting should be held in the early autumn for the consideration of the National Health Service Bill in its final stage in the light of the views of the profession, as expressed at the Annual Representative Meeting and in resolutions on the present agenda, and to determine future action.

Dr. O. C. Carter, chairman of the Journal Committee, presented recommendations for an increase in the editorial staff of the *British Medical Journal*, and these were approved. The Council also accepted proposals of the Staffing Committee that Dr. G. W. M. Findlay and Dr. S. S. B. Gilder be appointed editor and assistant editor respectively of the Abstracting Service, and that Dr. E. G. Murphy and Dr. D. Swinscow be appointed sub-editors of the *British Medical Journal*.

Dr. J. A. Pridham, chairman of the Organization Committee, presented the proposals concerning South African affiliation which on the following day were placed before the Representative Body and accepted (*Supplement*, August 3, p. 41). The Organization Committee was instructed to prepare the necessary amendments of articles and by-laws to provide for the new class of affiliated membership. It was agreed to inform the Federal Council in South Africa that the Council welcomed the proposal to appoint an observer to attend meetings of the Federal Council. Dr. Pridham also presented the report of the International Relations Committee and proposed that a sum of £1,000 be placed at the disposal of the committee for the session 1946-7 for the purpose of assisting selected British medical practitioners of high standing to give "B.M.A. Lectures" to the profession in various European countries. This was agreed to.

Psychiatry and the Law

Dr. R. G. Gordon presented a report by the Committee on Psychiatry and the Law—a joint committee of the B.M.A. and the Magistrates' Association, with observers from the Home Office, Ministry of Education, and Board of Control. The Criminal Justice Bill, which was introduced into Parliament in 1938 but not proceeded with, is likely to be reintroduced next session, and the committee made recommendations for its amendment, for transmission to the Home Office.

Dr. James Fenton dissented from a proposed amendment concerning offenders on probation or remand whose mental condition was considered to be such as required medical examination and might be susceptible to treatment. It was proposed

in the original Bill that such treatment should be by or under the direction of a duly qualified medical practitioner, but the committee wished to add the words "with experience of psychological medicine." Dr. Fenton considered that the addition of such words would create another example of the sectionalizing of the profession. They would all admit, he said, that whatever the branch of medicine concerned, no one could have too much experience; but that was very different from translating the requirement into an Act of Parliament. If this kind of thing went on—another example was the attitude of the Royal College of Obstetricians and Gynaecologists to the practice of midwifery by general practitioners—it would mean that after a man had spent six or seven years in studying medicine and had become qualified he would not be considered capable of practising without some further special qualification.

Dr. Gordon said that he fully appreciated the objection, but the Magistrates' Association—the other half of the committee—was very keen on this point. It was not a question of treatment but of giving expert opinion. He could not accept the responsibility of altering the recommendation without referring it back. It was agreed that this proposal, that the medical practitioner must have "experience of psychological medicine," should be withdrawn from the general body of the recommendations.

Assistance for Ex-Service Practitioners

Dr. Martin Brodie introduced a report by the Ex-Service Practitioners Committee. Attention had been drawn, he said, to the considerable number of temporarily registered practitioners who were holding hospital posts which might otherwise be available for ex-Service practitioners. The committee felt that the time had come when alien practitioners should be called upon to vacate their hospital appointments in order to expedite the absorption of ex-Service practitioners eligible for the more senior posts under the Government's postgraduate scheme.

It was agreed that representations should be made to the Ministry of Health that a greater number of Class III hospital posts be authorized to expedite the absorption of such practitioners; that the present restriction whereby only those ex-Service practitioners who could prove intention to specialize before recruitment to the Forces and were not established either in general or special practice were eligible for Class III appointments should be removed; and that Class III appointments should be open to ex-Service practitioners who had made progress in the direction of specialism during their service with the Forces.

The principal discussion centred round a recommendation that hospital appointments now held by practitioners who have not served with the Forces, including alien practitioners, should be re-advertised as soon as legally possible. Dr. R. G. Gordon suggested that after "Forces" the words "and who are not liable to do so" should be inserted, otherwise the hospitals were being asked to re-advertise the posts of practically all the staff who had not actually served in the Forces.

It was explained that the hospital appointments which it was suggested should be re-advertised were almost entirely "B1" appointments. The proposal was not intended to cover visiting staffs. On this point Col. A. H. Proctor pointed out that a good many of these "B1" appointments were in small hospitals which did not offer to the ex-Service practitioner the opportunities he wanted. The suggestion was made that the matter was covered by the Central Medical War Committee.

The Secretary explained that recruitable cases were constantly being examined by the Central Medical War Committee, but a substantial proportion of the jobs now under consideration were held by men who were ineligible for service on medical grounds and by alien practitioners.

Eventually the resolution was accepted in the following form:

That senior hospital appointments, including "B1" appointments, which have been held by their present occupants for two years or more, including those held by alien practitioners, should be re-advertised as soon as the relevant contract or agreement permits in order that demobilized practitioners may have an opportunity of applying for them, and that a communication be addressed to all hospitals urging that this step be taken.

It was further agreed to draw the attention of hospitals to the fact that there are now full specialists available for appointment to hospital staffs, and that it would be both in the hospitals' and in the national interest to review the staffing position now with a view to restoring it at least to the 1939 level and to increase the hospital establishments where possible. Dr. Carter pointed out that it would be a serious matter for part-time staffs, who would be squeezed out if hospitals were encouraged to increase their staff beyond the 1939 level, but an amendment to leave out those words was not carried. The committee had prepared an appendix setting out the problems of the ex-Service practitioner and the way in which they might be met. On certain points, including the present value of practices in terms of years' purchase, the committee undertook to look at the appendix again, after which it would be referred for office staff use in advising inquirers.

Some months ago the Council decided to withdraw its recommendation that medical appointments should continue to be made on a temporary basis. The question now arose whether the time had not come to discontinue the practice of insisting that, in advertisements of permanent medical appointments, two months should be allowed for the receipt of applications. Mr. Newell, chairman of the Hospitals Committee, recommended that this requirement be withdrawn, and that in future the Association should not insist on any minimum period for the purpose, and this was agreed to.

Other Committees

Mr. Dickson-Wright reported that the committee charged with the consideration of the composition and procedure of the General Medical Council had held two meetings and had deliberated on the method of dealing with penal cases—a very absorbing and intricate subject. It had been greatly helped by the two defence societies which had prepared a memorandum (*Journal*, July 6, p. 21). The committee had not yet arrived at any finality in its decisions.

Dr. H. R. Frederick presented a report of the Welsh Committee, with a memorandum by Dr. D. B. Evans on hospital services in North Wales. He said that the committee had discussed the position of Wales in relation to the administrative proposals in the National Health Service Bill and had reaffirmed the resolution of the Special Representative Meeting, '5, that Wales should be represented on the Central Health Services Council and the Medical Advisory Committee. The committee considered also that Wales should be administered as a region based on the Welsh National School of Medicine, but that satisfactory interim arrangements should be made in respect of areas more readily linked with university centres in England.

A report by the chairman of the Public Health Committee on the salaries of whole-time medical officers employed at mental hospitals and mental deficiency institutions, which roughly followed the lines of the interim "Askwith" document, was approved.

A report by the Building Committee concerned the ventilation of the council chamber, the lighting of the library, the use of the basement garage, and the letting of accommodation in the Association House.

FIRST MEETING OF NEW COUNCIL

A short formal meeting of the new Council was held on July 25, at the termination of the Annual Representative Meeting. Dr. H. Guy Dain was unanimously and with acclamation elected Chairman of Council for a further term.

New members of Council were welcomed. They were Sir Hugh Lett (President, *ex officio*), Mr. Lawrence Abel and Dr. W. D. Steel (elected by the Representative Body), Dr. Mary Esslemont and Dr. H. M. Golding (elected by Branches in Great Britain), Dr. J. H. Anderson, Dr. P. T. O'Farrell, Dr. Harper Nelson, and Mr. A. E. Porritt (elected by Branches outside Great Britain), and Surgeon Rear-Admiral W. H. Edgar (on recommendation of Council, to represent Royal Naval Medical Service).

The following Special Committees were reappointed: Protection of Practices, Compensation and Superannuation, Medical Curriculum, Public Relations, Rehabilitation, International Relations, Building, Parliamentary Elections, General Medical Council, Films in Medical Education, Ex-Service Practitioners, and Psychiatry and the Law. The committees on the relationship of the Association and the British Medical Bureau, on the Care of Children, and on the Treatment of Children under the Education Act, having completed their reference, were discharged. The Council also reappointed its members on the Joint Committee of the Association and the Trades Union Congress, the Joint Committee of the Association and the Pharmaceutical Society, and the Liaison Committee of the Association and the Royal College of Nursing. The nine practitioners representing the Association (in addition to the officers and chairmen of standing committees) on the Central Medical War Committee were nominated, and the Council confirmed the nomination of Dr. F. Gray and Dr. E. A. Gregg as representatives of the Association on the Council of the Society of Medical Officers of Health.

Following the approval of the interim agreement on the salaries of whole-time medical officers, it was intimated that it would be necessary to re-establish the Joint Advisory Committee set up under the original memorandum. This committee, although consisting predominantly of whole-time medical officers of health, has always had at least two practitioners from other fields, and indeed the spokesmen from the professional side of the committee (which is a joint committee with the associations of local authorities) have invariably been members who were not whole-time medical officers. Five names had been suggested from the public health side, and the Council nominated in addition Dr. J. W. Bone, Dr. F. Gray, and the Secretary.

The Council considered the date on which to hold a special meeting to consider the National Health Service Bill in its final form, the views of the profession upon it, and the course of future action. The meeting was fixed provisionally for October 9.

Correspondence

Delayed Release of Specialists

SIR,—You are probably weary of reading letters from disgruntled doctors in the Services. Perhaps you regard them as a collection of hysterical individuals who have lost all sense of proportion. Perhaps, Sir, you are right. But we did not start off our Service careers with those neurotic fixations and phobias. They have developed as a reaction—in many cases the only available reaction—to the irrationality and caprice of Service policies.

At the moment there can be few groups, anywhere in the world, of people of such a grade of intelligence and such training who demonstrate the phenomenon of mass anxiety to so marked an extent as the collection of specialists in the Forces whose Age and Service Groups lie between 35 and 50. They are penalized (the word is just) for being, in some cases, a bit more clever than the average and, in all cases, for having worked at their own job a bit harder than the average. And the form of the penalty is particularly malevolent—they are not to be allowed to do the work for which they are best suited. G.D.M.O.s may go, but specialists must remain and do the G.D.M.O.s' work—there being in most cases no work in their own specialty. Or, even worse, they are to stay and be company officers, part-time registrars, and general "stooges."

Our fault is, of course, that there are too few of us and our combined votes would be of little value in even a single

onstituency. We can therefore, being numerically negligible, be ignored by the politicians—national and medical. Such pleas as we make that our services are no longer required (and your correspondence columns show that that is at least a fairly general opinion among us) can accordingly be treated with contemptuous silence or by vague references to national as against individual needs. Even the most sanguine amongst us now knows that appeals for justice or even to common sense are fruitless. The baffled realization of our impotence aggravates our mental irritation and increases our painful laustrophobia.

I do not expect this letter to have the slightest effect on the rate of release of specialists in the forces. It has, however, had a slight cathartic effect on my own congested cerebrum, and as a purely therapeutic measure has perhaps been worth writing.—I am, etc.,

Secunderabad,

D. MACAULAY

SIR,—Stationed as we are, in the Far East, it is some time before we receive copies of medical journals, and we realize that by the time this letter reaches England many other similar ones may already have been published on what is to us the very pressing subject of demobilization of specialists in the R.A.M.C. All we know of the future rate of release of specialists contrasts most unfavourably with the general rate of release throughout the Army, and even with the rate of release of specialists after the last war, when large numbers were retained for indefinite periods after the war ceased.

The War Office announces that for the period July to September, inclusive, part of group 31 to part of group 40 will be released throughout the Army, except in the case of R.A.M.C. specialists, of whom groups 34 and 35 only will be released. Here we would emphasize that we are not asking for the accelerated release of the G.D.O. (group 50 by the end of September), but at the present rate many specialists face the prospect of a further two years' compulsory deferment, despite Mr. Morrison's statement that demobilization will be virtually complete by December 31, 1946. Added to this dismal prospect is the fact that we are not even eligible for L.I.A.P. (Leave In Advance of Python) to U.K. This leave is intended for all those who will have a further four months to serve in their overseas station on their return from U.K.; reckoning on the normal rate of release, only those over group 56 may apply. No allowance is made, however, for the compulsory deferment of specialists, so that a specialist of group 50, with the probability of at least a further eighteen months' service over-seas is still banned from applying for L.I.A.P. The points that we feel should be brought to the notice of the profession are these:

1.—Before the end of the European War an official representative of the E.M.S. stated to M.O.s in France that the release of specialists would be kept up to the standard rate of release throughout the Army by the call-up of civilian specialists. We can only infer that this call-up is not in fact taking place, since the demobilization of specialists is falling so far below the general rate.

2.—On account of the extreme disparity between the rates of release of G.D.O.s and specialists, no G.D.O. now applies for training in any specialty. Further, as a result of this rapid release of G.D.O.s, not only are there no young replacements for specialists forthcoming from within the R.A.M.C. itself, but also specialists are further penalized by having to do their own G.D.O. work on account of the shortage of G.D.O.s. If there is any shortage of doctors in the Far East, it is of R.A.M.C. G.D.O.s rather than specialists.

To sum up, what we ask is that the release rate of specialists be brought into line with age and service group release, and this, we believe, can be implemented by a further call-up of civilian specialists into the R.A.M.C.—We are, etc.,

"SEVEN SPECIALISTS."

The standing committee of the Bristol and District Divisional Hospitals Council at a recent meeting passed a resolution unanimously regretting that "the provisions under the National Health Service Bill for representation on Regional Hospital Boards, hospital management committees, and boards of governors of teaching hospitals do not give local interests the scope necessary for the maximum success of the proposed National Health Service."

H.M. Forces Appointments

ROYAL NAVY

Surg. Cmdrs. C. Keating, M.S.M., and R. C. May, O.B.E., M.C., to be Surg. Capt.

Surg. Cmdr. F. W. A. Fosberry has been placed on the retired list. Surg. Lieut.-Cmdrs. (Emergency) N. S. Heppburn, J. P. Corcoran, and J. C. Wyatt have been transferred to the Permanent List in the rank of Surg. Lieut.-Cmdrs.

Acting Surg. Lieut.-Cmdrs. (R.N.V.R.) R. S. P. Hawkins and G. A. S. Anthony have been transferred to the R.N. in the rank of Surg. Lieut.-Cmdr. and Surg. Lieut., respectively.

Temp. Surg. Lieuts. (R.N.V.R.) J. T. Morgan, M. P. Glanville, S. G. F. Linton, A. J. Sangster, R. S. McDonald, and A. W. Hagger have been transferred to the R.N. in the rank of Surg. Lieuts.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lieut.-Cmdr. R. D. Jenkins to be Surg. Cmdr.

Temp. Surg. Lieut. V. P. McDonagh to be Temp. Surg. Lieut.-Cmdr.

Temp. Acting Surg. Lieut.-Cmdrs. O. G. Lloyd and F. A. Hampton to be Temp. Surg. Lieut.-Cmdrs.

ARMY

Maj.-Gen. G. A. Blake, C.B., K.H.S., late R.A.M.C., has retired on retired pay.

Col. F. S. Irvine, C.M.G., D.S.O., late R.A.M.C., retired and re-employed, to be acting Major-Gen.

ROYAL ARMY MEDICAL CORPS

Lieut.-Col. C. L. Emmerson has retired on retired pay and has been granted the honorary rank of Col.

Lieut.-Cols. E. O. A. Singer and J. D'A. Champney, having attained the age for retirement, are retained on the Active List supernumerary.

Capt. (War Subs. Major) E. H. Evans and Capt. H. A. Bowker have retired and have been granted the honorary rank of Major.

Short Service Commissions.—War Subs. Majors J. J. Sullivan, P. Coleman, and R. G. Davies, Capt. (War Subs. Majors) P. H. Ball and O. W. W. Clarke and Capt. J. B. Plews, K. P. Brown, A. B. Fountain, N. G. G. Talbot, O.B.E., I. A. Walsh, J. H. McLaughlin, J. M. Laferla, F. G. Neild, J. J. McGrath, and A. Grieve, have been appointed to permanent commissions.

Short Service Commissions (Specialist).—To be Capt.: War Subs. Majors A. G. Wright, A. Torrie, and E. H. Larkin; War Subs. Capt. R. T. Wordingham and J. J. Voller; Lieuts. (War Subs. Capt.) R. T. Fletcher and J. C. Scott, from R.A.M.C., Emergency Commissions, and Capt. R. M. Henderson, from R.A.M.C., S.S.

Capt. L. A. S. Edmondson and W. A. Groom have retired.

Capt. A. B. Dick and Lieut. N. G. G. Talbot, O.B.E., from R.A.M.C., T.A., War Subs. Capt. D. L. Scott, Lieuts. (War Subs. Capt.) J. H. McLaughlin, R. G. Boyd, M.C., T. C. R. Archer, J. P. Mitchell, D. Macdonald, and S. H. Roe, from R.A.M.C., Emergency Commissions, and War Subs. Capt. H. A. Ferrante, from Royal Malta Artillery, Emergency Commission, have been granted short service commissions in the rank of Lieut. and to be Capt.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Senior Training Corps.—Major R. J. S. McDowall, supernumerary for service with Birmingham Univ. Senior Training Corps (Med. Unit) has resigned his commission. Lieut. A. S. Davie, supernumerary for service with St. Andrew's Univ. Senior Training Corps (Med. Unit) to be Lieut. Lieut. A. C. Lendrum, supernumerary for service with Glasgow Univ. Senior Training Corps (Med. Unit) has resigned his commission.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Subs. Lieut.-Col. (Local Brig.) A. E. Porritt, C.B.E., has relinquished the appointment of Consultant Surgeon and the local rank of Brig.

War Subs. Capt. R. G. A. Savage, W. E. David, G. A. Fraser, J. W. Anderson, R. P. Seymour, and C. T. Jones have relinquished their commissions, and have been granted the honorary rank of Major.

War Subs. Capt. A. Pearlman, P. X. Bermingham, and M. C. Chapman have relinquished their commissions on account of disability and have been granted the honorary rank of Major.

War Subs. Capt. T. A. Cox and D. Whitaker have relinquished their commissions and have been granted the honorary rank of Major.

War Subs. Capt. W. E. Brigg, W. H. Bennisson, G. L. G. Kiloh, and M. J. Pleydell have relinquished their commissions on account of disability and have been granted the honorary rank of Capt.

War Subs. Capt. R. Spicer.

A. Rusznak, V. Tausch.

I. Fischer, and I.

Lieut.

nursery and welfare-centre children

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

War Subs. Capt. (Mrs.) O. R. Major has relinquished her commission and has been granted the honorary rank of Capt.

War Subs. Capt. (Mrs.) M. Bergman has relinquished her commission.

ROYAL AIR FORCE

Fl. Licut. R. Mortimer to be Squad. Ldr. (War Subs.).

To be Fl. Lieuts. (Permanent): D. S. Grant, J. S. Howitt, and K. L. G. Nobbs, G.M.

ROYAL AIR FORCE VOLUNTEER RESERVE

Squad. Ldr. (honorary) R. J. Dyson has relinquished his commission on cessation of duty.

To be Squad. Ldrs. (Emergency): C. H. Catlin, M. L. Meade-King, and P. H. Sandifer.

Fl. Lieut. P. M. Peters has relinquished his commission on account of medical unfitness for Air Force service retaining the rank of Squad. Ldr.

To be Fl. Lieuts. (Emergency): P. L. Allen, A. F. Rushforth, J. M. Lipscomb, S. N. Nathan, C. E. Davies, and I. C. Simpson.

To be Flying Officers (Emergency): F. Alberts, G. J. E. Ansell, E. R. Arnold, T. C. G. Barnes, H. S. Bennett, F. M. Benton, J. H. Boydell, R. J. Bruce, I. Butler, H. E. Claremont, N. C. Connell, J. A. Cooney, W. G. C. Craigen, D. S. Cramond, R. Davidson, J. G. Duncan, C. W. Graham-Stewart, R. Horn, D. C. W. Jenkins, P. M. P. Jones, C. R. Kirkpatrick, R. F. Payne, P. A. Reed, D. F. Reynolds, C. Bannatyne, A. F. Bromwich, J. A. Clarke, L. G. G. Davies, D. W. James, E. G. Jenner, G. R. B. McCarter, H. B. Maliphant, A. D. Moffat, S. S. F. Munro, D. A. A. Parker, C. M. Ruben, J. F. Shaw, G. S. Tapsall, P. Vlasto, G. G. Wells, P. W. Wells, and F. R. M. Young.

Association Notices

CONSULTANTS AND SPECIALISTS COMMITTEE

Part-time Consultants and Specialists

Notice is hereby given of the formation by the Council of an electoral roll for the election to the Consultants and Specialists Committee of five representatives of members of the Association who are engaged part-time in consultant and specialist practice. Members of the Association who claim to conform to this definition, including those serving with H.M. Forces, are requested to complete and return the appended form to the Secretary, B.M.A. House, Tavistock Square, London, W.C.1, not later than Monday, Sept. 2, 1946.

CHARLES HILL,
Secretary.

Aug. 3, 1946.

BRITISH MEDICAL ASSOCIATION

CONSULTANTS AND SPECIALISTS COMMITTEE

Part-time Consultants and Specialists

FORM OF APPLICATION FOR INCLUSION IN ELECTORAL ROLL

to the Secretary,
British Medical Association,
B.M.A. House, Tavistock Square,
London, W.C.1.

I wish to apply for inclusion in the electoral roll for the election of representatives of part-time consultants and specialists on the Consultants and Specialists Committee. I am a member of the Association and am engaged part-time in the consultant and specialist practice of.....

Signed.....

A short formal meeting.....
July 25, at the termination of the.....
ing. Dr. H. Guy Dain was unanimously and.....
elected Chairman of Council for a further term.

The Katherine Bishop Harman Prize

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1947. The purpose of the prize, which was founded in 1926, is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child-bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present, provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1947, but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine. The decision of the Council will be final.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed, at B.M.A. House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1946.

Diary of Central Meetings
OCTOBER

9. Wed. Council, 10 a.m.

POSTGRADUATE NEWS

A series of special Edinburgh postgraduate lectures has been arranged, under the auspices of the Honyman Gillespie Trust, for the summer vacation. The lectures will be held in the West Medical Theatre, Edinburgh Royal Infirmary, on Thursdays, at 4.30 p.m., Aug. 15, 22, and 29, Sept. 12 and 19; and Oct. 3, and are open to all graduates and senior students. Details will be published in the diary column of the *Supplement* week by week.

WEEKLY POSTGRADUATE DIARY

EDINBURGH POSTGRADUATE LECTURES.—At West Medical Theatre, Edinburgh Royal Infirmary, *Thurs.*, 4.30 p.m. Dr. J. K. Slater, Trauma as a Cause of Organic and Functional Nervous Disease.

APPOINTMENTS

BIRMINGHAM UNITED HOSPITAL.—Honorary appointments. *Assistant Physicians*: G. S. Hall, M.D., M.R.C.P., C. G. Parsons, M.D., F.R.C.P., C. R. St. Johnston, M.D., M.R.C.P., J. M. Mallins, M.B., M.R.C.P. *Assistant Surgeons*: T. S. Donovan, M.Ch.Orth., F.R.C.S., A. L. d'Abreu, Ch.M., F.R.C.S., A. Innes, F.R.C.S., J. Leigh Collins, M.D., F.R.C.S., G. H. Baines, F.R.C.S.

CALEY, IZZA, B.Chir., D.P.H., Deputy Medical Officer of Health, Mansfield.
HAMPTSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—*Gynaecologist to Out-patients*, John Howkins, M.D., F.R.C.S., M.R.C.O.G. *Honorary Anaesthetists*, H. Walton, L.R.C.P., M.R.C.S., D.A.; G. C. Steel, M.R.C.S., L.R.C.P., D.A. *Ear, Nose, and Throat Surgeon*, E. Oliver Harris, F.R.C.S.

HULL ROYAL INFIRMARY.—Honorary appointments. *Physician*: E. O. Halliwell, M.R.C.P. *Surgeon*: A. Pavick, F.R.C.S. *Ed. Orthopaedic Surgeon*: R. C. Tatham, F.R.C.S. *Ophthalmic Surgeon*: D. D. Stenhouse, M.R.C.S., L.R.C.P., D.O.M.S. *Gynaecologist*: G. S. Brown, F.R.C.S. *Ed. Pathologist*: N. T. Whitehead, M.B., B.S. *Assistant Surgeons*: J. R. Blackburne, F.R.C.S., and J. I. C. Mason, F.R.C.S. *Assistant Ophthalmic Surgeon*: S. J. H. Miller, M.B., Ch.B., D.O.M.S.

LANCKENAU, N. I., M.D., Physician-in-charge of Physiotherapy Department, Queen Mary's Hospital for the East End, Stratford, E.

WORCESTER ROYAL INFIRMARY.—Honorary *Assistant Surgeon in Ear, Nose, and Throat Department*: I. W. MacGregor, M.B., Ch.B. *Assistant Radiologist*: A. Vickers, M.B., B.S., D.M.R.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

GOODWIN.—On July 27, 1946, at the Lindo Wing, St. Mary's Hospital, W.2, to Barbara (née Robertson), wife of Dr. J. F. Goodwin, M.D., M.R.C.P., a daughter—Jennifer Jane Blair.

HYLTON.—On July 20, 1946, at Leeds, to Lorna Christine (née Petersen), M.R.C.S., wife of W. H. Hylton, M.R.C.S., a daughter.

KWANTES.—On July 31, 1946, at the Maternity Unit, Carmarthen Infirmary, to Catherine Mary Sheara (née Griffiths), A.I.H.A., wife of Dr. Willem Kwantes, M.B., B.Chir., a daughter—Sheara Elizabeth.

MARTINEZ-ALONSO.—On July 26, 1946, at Queen Charlotte's Hospital, London, to Ramona, wife of Dr. E. Martinez-Alonso, a daughter—Patricia Ann.

SMITH.—On July 22, 1946, at 18, Collin Gardens, N.W.9, to Betty (née Gilbert), wife of Brian J. Douglas Smith, M.B., B.S. (London), a son—Nicholas.

DEATH

BROWN.—On July 20, 1946, Jane Ann (formerly Sister Johnston, Queens Hospital, Birmingham), beloved wife of Henry Skinner Brown, M.D., Leland House, Stakford, Choppington.

LONDON SATURDAY AUGUST 17 1946

THE HEALTH OF CHILDREN IN WARTIME DAY NURSERIES

A REPORT OF AN INVESTIGATION BY THE DAY NURSERIES COMMITTEE OF THE MEDICAL WOMEN'S FEDERATION, IN CONJUNCTION WITH W. J. MARTIN, Ph.D.

his investigation was sponsored and planned by the Day Nurseries Committee of the Medical Women's Federation.* The statistical analyses have been in the hands of Dr. W. J. Martin. All the medical examinations were carried out by doctors in the Public Health Service in a number of areas throughout the country.

Aim and Method of the Investigation

The purpose of the inquiry was to obtain data concerning the effect of life in wartime day nurseries on the health of young children. The present report describes one section of the investigation only—a comparison of children who had been in months or more on the register of a wartime day nursery (nursery group I) with two other groups: (a) children who had been less than one week in a day nursery (nursery group II); and (b) children attending welfare centres.

A comparison only with children attending welfare centres might be misleading, since economic and other factors may influence admission to a day nursery or attendance at a welfare centre. To eliminate differences between these two groups, so far as was possible, each nursery where the inmates were examined was paired with a welfare centre serving the same area, so that for each district the children were drawn from a roughly similar environment; further, in the records used for this report the children at any one day nursery and its paired welfare centre were examined by the same doctor and within one short period, which in most areas was less than a week and in no area longer than a fortnight. Nevertheless, it was recognized that even with these conditions the two groups are not necessarily strictly comparable. For this reason comparison was also made with children within one week of admission to a day nursery, as this group should show whether or not children on arrival at a day nursery were similar to welfare-centre children. Unfortunately it was not possible to examine the majority of these children on the first day of nursery life as would have been desirable.

The examinations were carried out by 73 medical officers in the course of their usual work. Each child was examined once only, and the records were limited, with one exception, to items about which there should be the minimum variation of opinion between doctors. The exception was an impression of the general health of the child, and it was recognized that this would be of value only if there were a large preponderance of opinion one way or the other. The records included sex, date of birth, date of admission (for nursery children), weight, and the presence or absence of the following signs of respiratory infection: enlargement of the tonsillar glands, nasal discharge, mouth-breathing, and physical signs of bronchitis.

Clinical Material

Children were examined in day nurseries and welfare centres in 22 local government areas in Great Britain. These included 14 county and non-county boroughs (3 in Scotland, 1 in Wales, 6 in Northern England, 2 in the Midlands, 1 in the West of England, and 1 on the outskirts of London), also 5 county areas (including small towns and semi-rural areas in Scotland

and Southern, Midland, and Northern England) and 3 London boroughs. All the examinations were made in the period February to September, 1945. The age range was from 6 months to 5 years. It proved impossible to obtain a similar age distribution in the different groups because of the relatively small number of young children attending day nurseries, and of older children attending welfare centres. The age distribution in the two major groups (nursery group I and welfare-centre group) is given in Tables II and III.

The report is based on the records of 4,587 children, made up as shown in Table I.

TABLE I.—Groups of Children Examined

	Males	Females	Total
Children on the register of a day nursery for 6 months or longer (nursery group I)	1,193	943	2,136
Children attending a welfare centre	1,094	1,067	2,161
Children on the register of a day nursery for 1 week or less (nursery group II)	158	132	290

For those unfamiliar with the implication of names such as day nursery, nursery school, and nursery class it may be as well to state that wartime day nurseries were established with the object—not necessarily fulfilled—of augmenting the country's labour force, that admission was therefore limited in the main to the children of mothers in employment, that the nurseries were usually open from 7 a.m. to 7 p.m. for 5½ or 6 days a week, and admitted children up to 5 years old. Each nursery was under the charge of a matron, usually a State-registered nurse, assisted by a certificated or uncertificated teacher, trained nursery nurses, nursery assistants (with a brief wartime training or none at all), and student nursery nurses. The approved complement of full-time staff (excluding domestic) was one to every five children. A nursery school or class does not admit children under 2 years old, and is under the direction of a certificated teacher, with assistants, and a visiting or whole-time nurse. Normally a nursery school is open only for the usual school hours, and, though they have often been open for longer hours during the war, it has not usually been for as long as the 12-hour day of the wartime day nurseries. The report deals with children in day nurseries only, but the findings observed would probably apply to some extent to any congregation of young children.

Comparison of Welfare-centre Children and those who had been Six Months or More on the Register of a Day Nursery

Tables II and III show separately for males and females in the welfare-centre group and nursery group I the percentage distribution of the various physical conditions on which information was sought.

Tonsillar Glands.—The doctors were asked to record these glands as being "not palpable," "just palpable," "intermediate," or "grossly enlarged." The last two classifications have been grouped together in the tables. Tonsillar gland enlargement of all grades was more common among children in nursery group I than among welfare-centre children, and the difference between the two was significant for both males and females. When these two groups are subdivided by age (five age groups for each sex—see Tables II and III) the difference between nursery and welfare-centre children is significant in five out of

* The following are the members of the Committee: Dame Janet Campbell, President of the Medical Women's Federation (*ex officio*), Dr. Katherine Hirst (Chairman), Dr. Beryl Harding (Hon. Secretary), Dr. Marjorie Back, Mary Boyd, Annis Gillie, Sylvia Guthrie, Helen Mackay, Jean Mackintosh, Mary Sheridan, and Nora Wallie.

the ten age groups. It is a curious fact that, although "just palpable" tonsillar glands were considerably more common among nursery children than among welfare-centre children, the greater degrees of enlargement were only slightly more common.

Nasal Discharge.—The doctors were asked to record nasal discharge as "not present," "present and observed" (i.e., observed by the doctor by ordinary external examination), or "stated to be present" (i.e., the nurse or mother stated that

children. The proportion with "reported" nasal discharge was larger among the welfare-centre children, and the difference was significant for all ages combined among boys, but not among girls. It is probable that there is a difference in the reliability of the information regarding "reported" nasal discharge, since in the welfare-centre group the mother of the child was questioned, but in the nursery group the matron or other member of the staff supplied the information; the results have, however been included for the sake of completeness.

TABLE II.—Incidence of Physical Conditions: Males. (Children affected shown as percentage of total number examined)

N. = children on nursery register for six months or more; C. = welfare-centre children. Significant differences are shown in italics.

the child had a "running nose" that day but it was not obvious at the moment of examination, owing probably to the child's having recently blown his nose). Any nasal discharge was included, either purulent or simple catarrhal. The proportion of children with observed nasal discharge was much greater among the nursery children than among the welfare-centre children, and the differences were significant for all ages combined, and for each separate age group except the youngest. Excluding those under 1 year old, nasal discharge was twice as common among nursery children as among welfare-centre

Mouth-breathing.—This was reported simply as "not present" or "present" at the time of the examination. Mouth-breathing was more frequent in the nursery group than in the welfare-centre group, and the difference between the two significant for all ages combined. In the individual age groups one male and two female age groups had significant differences.

Physical Signs of Bronchitis.—These were also reported simply as "not present" or "present." Bronchitis was more common among nursery children than among welfare-centre

children, and the difference for all age groups combined was significant among girls. In the individual age groups one female and two male age groups had significant differences.

Impression of General Condition.—The observers were asked to record their impression of the child's general condition as "very fit," "well," "fair health," or "poor health." Records on this point are obviously open to the criticism that doctors will differ in their classification. Nevertheless, it was thought worth while to obtain some indication of opinion, bearing in mind that with a large number of examining doctors individual variations may tend to be cancelled out. It is apparent from the individual records that, in general, the impression reported relates to the child's physique rather than to his state of general health, since many cases with well-marked evidence of respiratory infection were recorded as "well" or even "very fit." The classifications "very fit" and "well" have been grouped together in the tables. With the exception of the youngest age groups a larger proportion were described as "very fit" or

There was no consistent difference between the sexes in either group in the incidence of "just palpable" tonsillar glands, nor of bronchitis.

Closely similar proportions of boys and girls were recorded under "very fit" or "well" and under "fair health" in each age group of the welfare-centre children, but there are considerable and inconstant variations of these proportions for boys and girls in the different age groups of nursery children. The mean weight of boys was higher than that of girls at nearly all ages, among both nursery and welfare-centre children.

Comparison of Nursery Children within One Week of Admission with Those in the Other Two Groups

Children in the two major groups (nursery group I and welfare-centre) showed considerable differences, especially in the incidence of respiratory infection, but the question remains whether these were the result of nursery environment or whether there was already a difference between welfare-centre and nursery

TABLE IV.—Comparison of Mean Weights of Children who had been Over Six Months on Nursery Register with Mean Weights of Welfare-centre Children

Age in Months	MALES					FEMALES

TABLE V.—Comparison of the Observed Incidence of Infection in Nursery Children with the Expected Incidence, based on Welfare-centre Children

Evidence of Infection	Nursery Group II (Admissions)				Nursery Group I			
	Observed Incidence	Expected Incidence	Observed less Expected	Probability of the Difference occurring by Chance	Observed Incidence	Expected Incidence	Observed less Expected	Probability of the Difference occurring by Chance
	%	%			%	%		
Tonsillar glands:								
Just palpable	32.1	28.6	+3.5	0.5 > P > 0.3	42.2	32.7	+9.5	P < 0.01
Intermediate and grossly enlarged ..	8.3	10.3	-2.0	0.5 > P > 0.3	14.7	14.1	+0.6	0.8 > P > 0.7
All degrees of enlargement	40.3	38.9	+1.4	0.5 > P > 0.3	56.9	46.8	+10.1	P < 0.01
Observed nasal discharge	33.4	19.9	+13.5	P < 0.01	37.1	18.6	+18.5	P < 0.01
Mouth-breathing	27.2	23.4	+3.8	0.5 > P > 0.3	31.3	23.1	+8.2	P < 0.01
Bronchitis	9.0	9.5	-0.5	0.9 > P > 0.8	11.7	7.7	+4.0	P < 0.01

"well" among the nursery children than among the welfare-centre children. The differences at ages 3-4 and 4-5 years for females and 2-3 and 4-5 years for males were significant.

Weight.—Table IV gives the mean weights for males and females in three-monthly age groups. The total number of children is rather less than in the other tables, since in a few instances weight was not recorded. The nursery children were, on the whole, heavier than the welfare-centre children, although only four of the 18 male age groups and two of the female age groups had differences that were significant.

Sex Differences.—The ratio of boys to girls in nursery group I is 5 boys to 4 girls, and the preponderance of boys is apparent at each year of age. There is a slight preponderance of boys in the welfare-centre group as a whole but not in each separate age group. Although a comparison of the health of boys and girls was not a primary object of the investigation, the following observations are of interest. Boys in the welfare-centre group showed a higher incidence of observed nasal discharge at all ages than did the girls, but there is no consistent difference between boys and girls in the nursery group. Boys in both the welfare-centre and the nursery group showed at all ages a higher incidence of the greater degrees of tonsillar-gland enlargement. The same is true of the incidence of mouth-breathing (except in the 4-5-year-old nursery children).

children at the start of their nursery life. The records of the group who were examined within one week of admission to nurseries (nursery group II) throws light on this question. This group of 290 was made up of small numbers of children scattered all over the country, and may be regarded as reasonably typical of that section of the community from which the nursery population was drawn. It would be unreliable to compare the children in this group, age for age, with those in the two major groups, because of the small numbers. Nevertheless, they can be compared by calculating the observed and expected incidence of infection in the groups as a whole, using the incidence in the welfare-centre children of similar age and sex (as shown in Tables II and III) to calculate the expected incidence in the nursery groups. Table V shows this comparison. The columns headed "Observed Incidence" show the percentage of children in each group suffering from the various defects, as actually observed. Those headed "Expected Incidence" show what would have been the percentage affected in each group had the defects occurred in the same proportion at each year of age as they occurred at that age in the welfare-centre children. In other words, the table shows the incidence of infection that would have been expected had the nursery children been similar to the welfare-centre children in respect of respiratory infection.

In the nursery admission group the differences between the observed and expected incidence of defects show that these children had in fact a slightly lower rate than might be expected of some defects and a slightly higher rate than expected of other defects, and that only for nasal discharge is the observed incidence considerably greater (by 67%) than the expected incidence. Statistical interpretation of these figures indicates that only for nasal discharge is the difference greater than might occur by chance. It should be remembered that these children were examined within one week of admission, not on the first day in a nursery. The fact that nasal discharge was the only evidence of respiratory infection in which the observed incidence was significantly greater than would be expected, and was, moreover, strikingly greater, suggests that a considerable proportion of these children had developed a cold during the first week after admission. Were this not so it would be reasonable to expect that the other signs of respiratory infection would have also shown significant differences between observed and expected incidence.

In the group of children who had been six months or more on the register of a nursery the observed incidence of infection is greater than the expected incidence for every defect recorded. The observed incidence is 100% greater than the expected incidence for nasal discharge, 29% greater for "just palpable" tonsillar glands, 22% greater for all degrees of tonsillar-gland enlargement, 36% greater for mouth-breathing, and 52% greater for bronchitis. The probability that the

Discussion

The data show that children who had been on the register of a wartime day nursery for six months or more had a much higher incidence of respiratory infection than those attending welfare centres in the same localities. The difference was present in all age groups and in both sexes. When all the defects observed are taken into consideration the 2-3-year-old groups showed the greatest difference. Further, the increase in the evidence of respiratory infection was not attributable to significant differences between welfare-centre and nursery children at the start of their nursery life—with the doubtful exception of some part of the increase in the incidence of nasal discharge. On the other hand, the data show that the nursery children were on the whole heavier than the welfare-centre ones, and the differences between the observed and expected mean weights of the nursery children were significant for those over 2 years of age. In support of this, also, more nursery children were recorded as "very fit" and "well" in the upper age groups than in the same age groups of welfare-centre children.

The scope of the evidence is admittedly limited, but so far as it goes it does not indicate a beneficial effect of nursery life for the younger children—rather the reverse. There was a general increase of respiratory infection, to a significant extent in some instances, but no constant or significant improvement in physical development as indicated by weight or the doctor's impression of general physique. For the older children, the

Significant differences shown in italics.

difference between observed and expected incidence is due to chance is negligible for every defect except "intermediate and grossly enlarged" tonsillar glands.

This comparison of the two nursery groups with the welfare-centre group indicates that the high incidence of respiratory infection in children who have been six months or more on a nursery register is not accounted for by significant differences between welfare-centre and nursery children at the start of their nursery life. The only difference between them was in respect of nasal discharge, but this was of doubtful significance, for the reason already given. Moreover, though the observed and expected incidences of nasal discharge were not the same in children within one week of admission to nurseries, there was a much greater discrepancy in those who had been in nurseries for more than six months.

The observed mean weights of the children at each year of age in the two nursery groups have similarly been compared with the expected mean weights based on the welfare-centre children, and the results are shown for males and females separately in Table VI. Although the observed mean weights for the admission group of children are in the main below the expected mean weights, the differences are not significant for the total of males or females. For the children six months or more in a nursery the differences between the observed and expected mean weights are significant in each age group over 2 years for both males and females, and for the total of males and females. For the group as a whole the mean weight of boys was 0.7 lb. (317.5 g.) greater than would be expected on the basis of welfare-centre children, and the mean weight of girls 0.5 lb. (226.8 g.) greater, in spite of the fact that there was no significant difference in weight between welfare-centre and nursery children at the start of their nursery life.

effect of nursery life, as reflected in the investigation, was partly adverse and partly beneficial. There was a considerable increase in respiratory infection, but also a definite improvement in weight and physique. Certain points should be borne in mind in considering these facts.

The investigation was planned solely with reference to certain aspects of the physical health of the children. It does not attempt to deal with the social or economic aspects of day nurseries, nor with their effect on the mental health and development of the children. Only wartime day nurseries could be considered—that is, nurseries run under difficulties inherent in wartime conditions. Such factors as unsuitable premises, long nursery hours with early-morning and evening journeys, shortage of staff, and inadequately trained staff may well have influenced the incidence of respiratory infection. But in the absence of data relating to large numbers of children in nurseries not handicapped by these conditions it is impossible to assess just how far such factors may influence the occurrence of infection when young children are congregated together. On the other hand, wartime conditions were not wholly unfavourable to day nurseries. The extra milk, meat, cheese, fats, and other foods available to nursery inmates, over and above their rations at home, made it possible for nursery children to have a more satisfactory diet than non-nursery children, who were limited solely to their share of the family rations, and this no doubt contributed to the improved physique of the former. This difference in diet might not be so marked under normal conditions when the purchase of food for children at home is not limited by rationing.

The evidence of respiratory infection was necessarily limited to the less severe conditions that did not preclude a child from admission to a day nursery or from being brought to a welfare

centre. Wartime day nurseries have been used almost entirely for the children of mothers going out to work, and there is reason to expect that nurseries will continue to be used mainly by mothers who are at work or who have pressing domestic or housing difficulties. In these circumstances, mothers, and perhaps nursery staff, may tend to disregard minor ill-health, so as to avoid the hardship that may result from excluding the child from the nursery. Such a state of affairs may contribute to the incidence of respiratory infection, and in itself help to create the risk of such infection.

Conclusions

It is perhaps unwise to attempt, from these limited findings, to assess the value of day-nursery life to children, since many factors have necessarily been left out of account. The outstanding fact is the constant and considerable increase of respiratory infection, and the question arises of its importance in considering the well-being of a community of young children. The whole answer cannot be given without further research, and may well involve considerations which elude statistical investigation. This report deals with only one part of the investigation undertaken by the Day Nurseries Committee of the Medical Women's Federation. A further report is in preparation, and will cover work carried out by Dr. Margaret McLaughlin, on behalf of the Federation, in observing the health of children in day nurseries and welfare centres of one city over a period of twelve months.

From the collated observations of many independent observers here presented it can be said with certainty that they clearly demonstrate the existence of a high incidence of respiratory infection in wartime day nurseries, and that this constitutes a risk to health demanding careful consideration in weighing the value of day-nursery life to an individual child or to a community of children.

Grateful acknowledgment is made to Prof. Ryle and Dr. Russell, of the Institute of Social Medicine, Oxford, and to Sir Wilson Jameson, Chief Medical Officer, and Dr. Dorothy Taylor, Senior Medical Officer for Maternity and Child Welfare, Ministry of Health, for advice in planning the investigation; to medical officers of health for their co-operation; and especially to the many assistant medical officers of health whose work in examining the children made the investigation possible.

THE AFTERMATH OF PERFORATED PEPTIC ULCER

BY

WILLIAM HOUSTON, M.Ch., F.R.C.S., F.R.C.S.I.

Surgical Registrar, Royal Free Hospital, London; Late Surgical Registrar, Royal Victoria Infirmary, Newcastle-upon-Tyne

Perforation of a peptic ulcer is an accident of supreme importance to the patient, for it places his life in jeopardy. It also results in considerable economic loss, and as similar factors probably underlie the onset of peptic ulceration and the causation of perforation no apology is necessary for another review of this subject.

The incidence of peptic ulcer, especially duodenal, has risen enormously in the past 20 years (Tidy, 1944), and more especially in the early years of the recent conflict (Stewart and Winsor, 1942). O'Donohue and Jacobs (1942) state that at their clinic there has been a 300% increase in the past 10 years. They quote De Bakey as stating that, in his experience, the incidence of peptic ulceration has risen from 443.7 per 100,000 hospital admissions in 1929 to 614.3 in 1938, and of perforation from 13.9 per 100,000 hospital admissions in 1929 to 78.3 in 1938.

Aim and Scope of Present Study

The following series is presented with full foreknowledge of its manifold defects. It represents an attempt to evaluate the late results of simple suture of perforated peptic ulcers in patients upon whom this operation had been performed 12 or more years previously. The material for this investigation comprised all cases of perforated peptic ulcer admitted to the Royal Victoria Infirmary, Newcastle, during the years 1929-32 inclusive. To these patients a questionnaire was sent which they

were asked to bring to the hospital for completion, and examination, and, if this was impossible, to take to their local practitioner for completion. No effort was made to trace those who were more than 55 years of age at the time of operation, and in order to obtain a uniform standard all who attended hospital were examined by the writer.

Results

The total number of letters dispatched was 538, and replies were received from 244, or rather less than half. Of the 244 replies 33 contained the news that the patient had died in the interim—11 from various other causes, 6 from "stomach trouble," and 16 from causes not mentioned. Of the remaining 211, 170 attended for examination and 41 merely returned the completed questionnaire.

(a) INCIDENCE

One of the most disturbing features about the majority of recent reports on the subject of peptic ulceration is the large rise in numbers noted. Illingworth *et al.* (1944) in a recent comprehensive study reported a rise in admissions of perforated peptic ulcer cases from 200 in 1929 to 600 in 1940 in an area where population changes had been minimal. The incidence of perforated peptic ulcer appeared to have risen from 11 per 100,000 in 1924 to 25 per 100,000 in 1938. Other writers, as previously mentioned, have noted a similar upward tendency.

The area drained by the Royal Victoria Infirmary is extensive, and any tendency to change in the population has been in a downward direction. Thus the ratio of admissions for perforated duodenal ulcer to total surgical admissions should be a fair indication of any change in incidence.

Year	Total Surgical Admissions	Total Perforated Duodenal Ulcers	%
1926	7,192	186	2.59
1931	6,931	156	2.25
1937	6,862	181	2.64
1938	6,909	198	2.87
1939	6,785	199	2.93
1940	6,418	221	3.44
1941	6,181	242	3.92
1942	6,253	156	2.49
1943	7,113	202	2.84
1944	7,240	205	2.83

There has been a slight rise in incidence between 1926 and the years from 1938 onwards. The greater rise during the dark days of 1940 and 1941 would seem to indicate that the "functional" element in peptic ulceration has not received the attention it merits.

(b) MORTALITY RATE

Year	Total Numbers	Deaths		Ratio
		No.	%	
1939	178 R.D.U.	22	12.4	R.D.U. : R.G.U. ... 8.5 : 1
	21 R.G.U.	4	19.0	Male, 194 : female, 5 ... 39 : 1
1940	193 R.D.U.	25	13.0	R.D.U. : R.G.U. ... 7 : 1
	28 R.G.U.	3	28.6	Male, 207 : female, 14 ... 15 : 1
1941	217 R.D.U.	22	10.1	R.D.U. : R.G.U. ... 8.5 : 1
	25 R.G.U.	6	24.0	Male, 229 : female, 13 ... 17.5 : 1
1942	138 R.D.U.	22	16.0	R.D.U. : R.G.U. ... 7.6 : 1
	18 R.G.U.	2	11.1	Male, 147 : female, 9 ... 16 : 1
1943	184 R.D.U.	15	8.2	R.D.U. : R.G.U. ... 10 : 1
	18 R.G.U.	6	33.3	Male, 193 : female, 9 ... 21.5 : 1
1944	190 R.D.U.	12	6.3	R.D.U. : R.G.U. ... 12.6 : 1
	15 R.G.U.	0	—	Male, 195 : female, 10 ... 19.5 : 1

Several points of interest emerge from these figures. First, the large preponderance of males, the ratio of males to females being at least 15 to 1. Griswold and Antoncic (1941) found this ratio to be 26 to 1, and Berson (1942) 31 to 1. Secondly, the confirmation of the accepted figure of 8 to 1 for the ratio of ruptured duodenal ulcer to ruptured gastric ulcer. And, thirdly, the not inconsiderable mortality, and the improvement which sulphonamides have effected. I think the reduction in the mortality rate in 1943 and 1944 must be due in large measure to the correct use of drugs of the sulphonamide group, though it may not be out of place to record that in 1932 Gilmour and Saint reported a personal series, from this same hospital, of 64 cases with an overall death rate of 4.7%. This is an achievement of which they have every reason to be proud, as most published figures give a much higher rate. Donald and Barkett (1942) had

an 18.5% death rate, and *Monro* (1945) states that most hospital series show a mortality of 20 to 25%, with little change in the last 10 years.

Late Results

Of the 244 patients who were traced, 33 had died, as already mentioned, 41 replied by post, and 170 attended for examination. I have kept these two latter groups separate, as postal replies are notoriously unsatisfactory. It will be noted that in referring to results I have studiously avoided the word "cure," and have preferred to speak of those who have had no symptoms, or otherwise. This is the only accurate way to consider results, and gives an idea of how I tried to sift the cases. Any patient who gave a history of periodic attacks of indigestion, however mild, was classed as a failure; and in the cases examined, even if there was no such history, any sign of stomach retention or dilatation or duodenal tenderness was regarded as evidence of a still active lesion. This clinical assessment must be the most accurate available, since x-ray examination will always show a deformed duodenal cap after suture of a perforation (*Lewisohn*, 1928, 1937; *Harrison and Cooper*, 1942).

Replies by Post.—41 patients: 40 R.D.U. (no further symptoms, 14, or 35%; some further symptoms, 26, or 65%), 1 R.G.U. The ruptured gastric ulcer had had further symptoms. Of the 26 with symptoms, 12 had required some further operation—3 for another perforation, and the remainder mainly for pyloric obstruction.

Attended for Examination, 170 Patients.—This total included 4 women, two of whom had had perforated duodenal ulcers and two perforated gastric ulcers, each pair presenting one symptomatic cure and one failure. It also included 7 cases of perforated gastric ulcer; six of these had had further symptoms, and one was symptom-free. This leaves 161 cases of perforated duodenal ulcer for analysis, which may be classified broadly thus: no further symptoms, 61 (38%); further symptoms, 100 (62%). Of those patients who had further symptoms, 33 (33%) required further operation, 1 had had later perforations, 1 gastrectomy, and the remainder gastro-enterostomy or some form of pyloroplasty. These figures are instructive in that they show that at least 20% of patients suffering perforation of a duodenal ulcer require further surgical intervention, and that of those who fail to obtain relief after suture of a perforation at least 26% will need some further operative procedure. It would also seem that there is a better prospect of symptomatic relief after perforation of a duodenal ulcer than of a gastric ulcer, though the number of the latter is too small to permit definite conclusions to be drawn.

Factors Affecting Symptomatic Cure

In an attempt to discover the factors influencing the relief of symptoms, these results were further analysed in three ways: (1) The chronicity or otherwise of the ulcer at time of perforation. The type of ulcer was based on the length of history rather than on operative findings, which are not very reliable. (2) The age of the patient at time of operation. (3) Whether or not any attempt to remain on a diet had been made after operation.

Results of Analysis

1) **Length of History.**—Of the patients tabulated below 38.9% said that the first indication of ulceration was perforation, and this was checked against the history given before operation. Of these, 22 had remained symptom-free and 16

	History less than 1 Year		History more than 1 Year		Total
	Symptomless	Return of Symptoms	Symptomless	Return of Symptoms	
By post ..	6 (15%)	7 (17.5%)	8 (20%)	19 (47.5%)	40
Attended ..	26 (16%)	34 (21%)	43 (27%)	58 (36%)	161

had had later dyspeptic symptoms. From the table it would appear that in those who have suffered perforation of a duodenal ulcer the odds are about 4 to 3 in favour of recurrence, whether the duration of symptoms be long or short. However, when perforation is the first symptom of ulceration the chances are 3 to 2 in favour of symptomatic cure.

(2) **Age of Patient at Time of Perforation.**—For this analysis the patients have been arranged in 5-year groups, and the percentage of symptomatic cures or failures in each group is expressed graphically (Figs. 1 and 2). When subdivided in this way the numbers in each group become relatively small, and inferences must therefore be drawn with caution. But it does seem that the prognosis is better in the higher age groups.

FIG. 1.—Showing results of perforation, at different ages, of those replying by post.

FIG. 2.—Showing results of perforation, at different ages of those who attended examination.

(3) **Effect of Diet.**—In this connexion dieting connotes sincere effort on the part of the patient to avoid foods which disagree with him and to follow the main principles of dieting i.e., regular small meals and avoidance of rough or high seasoned foods. It is virtually impossible for most patients to follow a strict regimen outside hospital. Of the 40 patients who replied by post, 14 were cured of symptoms, and, of the 6 (41%) dieted. Among the 26 with recurrent symptoms (50%) dieted. Of the 161 who attended for examination, symptomatic cure resulted in 61 cases, 13 (21%) of them having dieted. Among the 100 patients who returned with recurrent symptoms, 44 (44%) dieted. These figures require caution in their interpretation, but they would seem to indicate that perforated duodenal ulcers, dieting, unless of the strict nature possible only under hospital conditions, is of relatively little value. In this connexion it may not be amiss to consider allied questions of the effects of alcohol and tobacco. The great majority of those who smoked before operation continued to do so afterwards, though sometimes reducing amount, and the same finding obtained regarding the consumption of alcohol. Of the whole series 10 (4.7%) patients had given up or considerably reduced their consumption of tobacco. No non-smoker had started smoking after operation. Nineteen (9%) patients had become teetotal or almost so, but seven who had never taken alcohol before operation turned to beer and even stronger beverages for solace afterwards. One philosopher had discovered what Sir Hugh Devinc (1940) called the "water cure" for ulcer pain, and extolled the virtue of beer in "flushing acid out of the system." Many patients found beer necessary as a laxative, or discovered some other imperative reason for continuing their potations. Of the ulcer patient it may well be asked, "Can he change his habits?" and it would seem that any treatment which depends for success on such drastic change is doomed to failure.

Discussion

In the main the results of this investigation are confirmatory of work reported by other writers and bring little in the way of new facts to light. But some controversial points have arisen. For example, why should the incidence of perforation show such a slight increase in this area, where all the environmental factors are favourable to the production of such lesions—poverty and unemployment, old-fashioned housing, and the underground work?

Then there is the question of mortality. The fact that it is still high in spite of all modern aids should encourage practitioners to send all doubtful cases to hospital, as procrastination is so lethal.

The great difference in incidence of this complication between males and females is another perplexing aspect. Undoubtedly, aggravating factors are not so prominent in the lives of most women, and they have much better opportunities for regular meals. But it would seem that there must be some fundamental difference.

Perforated gastric ulcers are a great deal less common than duodenal, which is fortunate, as their mortality in general is much higher; over the whole six years for which figures were given, the mortality rate for perforated duodenal ulcer was 10.7%, while for perforated gastric ulcer it was 20.8%. This agrees with Tidy (1945).

The late results with reference to alleviation of symptoms are in agreement with those of most recent authors. In the period 1920-30 several reports of very high "cure" rates were published—e.g., Stewart and Barber (1922) reported 28 cures out of 37 cases treated by simple suture. In 1925 Grey Turner in a Hunterian lecture recorded 81 cures out of 120 cases, and in the ensuing discussion R. P. Rowlands said that only 25% had further symptoms. Pannett, writing in 1928, thought 50% were cured by simple suture. But towards the close of this decade more critical appraisal of results showed that only 30 to 40% of cases so treated remained symptom-free. Gilmour and Saint (1932) reported 64 cases, with 38% satisfactory afterwards, Sallick (1936) 9 cases symptom-free out of 33 cases traced, and Scotson (1933) 42% symptom-free after 3 years.

In the present series 38% of such patients have remained symptom-free 12 or more years after operation. This confirms the work quoted, and tends to support the belief that recurrences usually betray themselves within two years of operation or not at all. There are exceptions to this rule, which appeared to be true in the present series, though patients' memories are not entirely reliable. Five years is the longest interval after which symptoms recurred.

An old-established belief that the more chronic the ulcer the less the likelihood of cure is challenged by the figures I have advanced. The "cure" rate in those whose symptoms had lasted less than one year was 43% (26 out of 60), while in those in whom symptoms had lasted more than one year it was 42% (43 out of 101). Brown (1925) also challenged this belief, and stated that patients with no previous history fared worse, as regards return of symptoms, than those with long-standing histories. But of the 38 patients who had had no symptoms beforehand, 22 (57.9%) remained symptom-free, which would seem to indicate that in this group the prognosis is relatively good. And Gilmour and Saint (1932) had excellent results in all their cases with short histories.

One further point requires some elaboration, and that is the effect of diet on the rate of recurrence. Most authors are agreed that perforation should be followed by a strict medical ulcer regimen, and doubtless this counsel of perfection is the ideal towards which we should strive. But, human nature being what it is, ideals are seldom attained, and the figures I have gathered seem to suggest that nothing less than a strict diet is of any value. Only 21% of those who remained symptom-free after operation had made any serious attempt to diet, whereas 44% of those in whom symptoms recurred had made such an effort. Scotson (1933) stated that diet post-operatively had a very definite effect in reducing recurrence of symptoms. Cutler has always stressed the importance of such measures, and undoubtedly they are most important. The point I wish to make is the uselessness of half-hearted measures: if results are to be worth while a strict regime is essential.

Summary

The general results of simple suture in treatment of perforated peptic ulcers have been traced in a series of 244 cases which had been operated on 12 years or more ago.

The mortality rate of perforated peptic ulcer has declined since the introduction of the sulphonamide drugs.

Symptomatic cures were obtained in 38% of cases.

The prognosis with regard to symptomatic cure is better in patients with no preceding symptoms and in those in whom perforation occurs after the age of 45.

Diet, unless rigidly supervised and enforced, exerts little effect on the late results.

Alcohol and tobacco, although tending to aggravate symptoms, continued to be enjoyed by most patients accustomed to them.

I would like to thank all the members of the surgical staff of the Royal Victoria Infirmary, Newcastle-upon-Tyne, past and present, for permission to use and publish their case records. I should also like to thank Mr. Rodney Maingot for much helpful advice in the preparation of this paper.

MENINGITIS DUE TO A PENICILLIN-SENSITIVE, SULPHONAMIDE-INSENSITIVE PITTMAN b STRAIN OF *H. INFLUENZAE*: RECOVERY

BY

CONSTANCE F. DRYSDALE, M.B., B.Sc.

D. G. MCINTOSH, M.B., D.P.H.

Public Health Department, Dundee Corporation

AND

J. BRODIE, M.D., D.P.H.

Bacteriology Department, University of St. Andrews

In a previous publication (McIntosh and Drysdale, 1945) a case of recovery from *H. influenzae* meningitis (Pittman b type) in a child aged 2½ years following treatment with penicillin and sulphamezathine, to both of which the organism was sensitive, was described. The following case is of interest since (a) the causal Pittman b type of *H. influenzae* was penicillin-sensitive but sulphonamide-insensitive; (b) recovery ensued after prolonged treatment with penicillin.

Case Report

A male child aged 20 months was admitted to King's Cross (Infectious Diseases) Hospital, Dundee, on Dec. 18, 1945, with a three-days history of stiffness of the right leg, tenderness of the spine, and vomiting. Examination revealed bead retraction, presence of Kernig's sign, absence of abdominal reflexes, absence of knee-jerks, indefinite plantar reflexes; temperature 100.8° F. (38.2° C.), pulse rate 128, respiration rate 60. Lumbar puncture yielded a turbid fluid under increased pressure containing 383 cells per c.mm., of which 260 were red blood cells, and 75 mg. of protein per 100 ml. Sugar was absent. On Dec. 20 the preliminary bacteriological report stated that a micro-organism, probably *H. influenzae*, which was sensitive to penicillin and very slightly sensitive to sulphathiazole, but insensitive to sulphapyridine, sulphamezathine, and sulphadiazine, had been cultured. Detailed examination proved that the bacillus was a *H. influenzae* Pittman b type and quite insensitive to the above sulphonamides and also to sulphamerazine. *In vitro* tests showed that growth was noticeably inhibited in haematin broth containing 0.6 unit of penicillin per ml., and completely inhibited in a concentration of 0.7 unit per ml. Until the diagnosis had been established and full sensitivity tests completed 25 g. of sulphonamide (7 g. sulphapyridine, 5.5 g. sulphamezathine, 12.5 g. sulphathiazole), 125,000 units of Seitz-filtered penicillin intrathecally, and 900,000 units of penicillin intramuscularly were administered during Dec. 18-26. Thereafter penicillin alone was given. During the period Dec. 18-Jan. 21, 1,005,000 units were given intrathecally and 10,237,500 units intramuscularly (see Chart). The child's condition gave rise to anxiety until Jan. 10, when, with his reserves of strength almost depleted, and having made a good recovery from a convulsion (Jan. 8), probably induced by penicillin, he remained apyrexial, except for a slight elevation of temperature on Jan. 21 and 22, until he was discharged, recovered, on March 1. Clinically the most notable features of the illness were: head retraction (Dec. 18-23); the persistence of neck rigidity (Dec. 18-Jan. 14); intention tremors of

head and upper limbs (Dec. 18-Jan. 23); the occurrence of bronchopneumonia (Dec. 24-30) despite the antecedent penicillin-administration; the daily recurrence of a blotchy erythematous rash about two hours after the intrathecal injection of penicillin—appearing first on the thighs, then on the lower abdomen, followed by some blotchiness of the face, next morning found only on the thighs (Jan. 13, 16-18). The persistent nature of the meningeal infection is reflected also by the results of examination of the C.S.F. shown in the Chart. After the fluid had become clear and the culture sterile on Dec. 24, omission of lumbar puncture on Dec. 25 and 26 was followed by the recurrence of turbid C.S.F. on Dec. 27-Jan. 2 and by positive cultures on Dec. 27, 29, 30, and Jan. 3. Thereafter the pleocytosis diminished and a series of negative cultures was obtained. From Dec. 29 the daily intrathecal dose of penicillin was increased to 50,000 units until Jan. 8, on which date, owing to the occurrence of a convulsion about three hours after the injection, the dose was reduced to 30,000 units (Jan. 10) and to 25,000 units (Jan. 11-20). It is to be noted, however, that, using the method

2.0 units per ml. (with an average of 1.7 units per ml. for four days). While this concentration was adequate, as judged by the *in vitro* tests, for the inhibition of the causal strain, a reduction of the intrathecal dose to 25,000 units daily, despite the continuance of 500,000 units daily systemically, resulted in a concentration of penicillin in the C.S.F. which was in excess of the minimum *in vitro* level on only two of the nine occasions on which estimations were made (average for nine days, 0.1 unit per ml.)

Smith, Duthie, and Cairns (1946), referring to the danger of intrathecal treatment with penicillin, point out that excessive dosage (40,000 units and over at a single injection) may produce fits or other severe cerebral reactions when injected into the ventricles, or damage to the cauda equina or gumming of the subarachnoid space when injected by the lumbar route. I McIntosh and Drysdale's (1945) case myoclonic movements of

of Brodie (1945), the penicillin content of the fluid as estimated 20 to 24 hours after the previous intrathecal injection showed 2.0, 2.0, 1.7, 1.0 units, respectively, on Jan. 5-8 (average, 1.7 units). After the dose had been reduced to 25,000 units the daily values were only 0.5, 1.5, 0.25, 1.0, 0.5, 0.5, 0.2, *nil*, and 0.5 units, respectively, for the period Jan. 11-19 (average, 0.6 unit).

Discussion

in vitro sensitivity tests conducted by Gordon and Zinnemann (1945) showed that with 2.5 units of penicillin per ml. of medium the growths of 16 of 18 meningeal strains of *H. influenzae* were completely inhibited and those of the remaining two strains showed marked inhibition. Accordingly they recommended that it would be necessary to administer penicillin intrathecally (in addition to systemic dosage) so as to obtain a concentration of at least 2.5 units per ml. in the C.S.F. at the outset. "Later, more exact determination of the penicillin sensitivity of the particular *H. influenzae* strain isolated and assay of the penicillin content of the cerebrospinal fluid should serve as a guide to the further dosage to be given." The results obtained in the present case indicate that, even with a dosage of 200,000-500,000 units systemically and 50,000 units intrathecally daily, the penicillin content of the C.S.F. is, at least towards the end of the 24-hour period, not greater than

the face, arms, and lower limbs occurred five minutes after an intrathecal injection of 50,000 units by the lumbar route, and in the present case a fairly severe convulsion took place about three hours after an injection of 50,000 units by the same route. In each of these cases the convulsion occurred after the meningeal infection had been brought under control, as evidenced by sterile cultures, and there seems little doubt that the reactions were directly due to the penicillin. Smith, Duthie, and Cairns (1946) suggest that a single daily intrathecal injection of from 3,000 to 16,000 units is usually adequate to achieve the 0.03 to 0.06 unit per ml. concentration in the C.S.F. necessary for the control of the pneumococcal infections they have encountered. The findings of McAdam *et al.* (1945) accord with the view that the passage of penicillin into the C.S.F. depends on the breakdown by inflammation of the blood-brain barrier. They were unable to demonstrate penicillin in the C.S.F. of any of seven normal subjects who received a dosage of penicillin intramuscularly varying from 100,000 to 500,000 units. In persons suffering from meningitis and post-meningitic encephalitis adequate amounts of penicillin passed into the C.S.F. The results are not expressed in units per ml., but it seems unlikely that the concentrations would have approached the levels required for the control of *H. influenzae* infections.

The findings in the present case suggest that the necessary concentration of penicillin required to inhibit *H. influenzae* may not be maintained unless dosages greater than 25,000 units intrathecally are given, daily.

Summary

A case of *H. influenzae* meningitis in a male child aged 20 months is described. The organism belonged to the Pittman b type, and was sensitive to penicillin in a concentration of 0.7 unit per ml. and insensitive to sulphapyridine, sulphamezathine, sulphadiazine, ulphathiazole, and sulphamerazine. Complete recovery followed prolonged treatment with penicillin.

Estimations of the penicillin content of the C.S.F. showed that concentrations between 1.0 and 2.0 units (average, 1.7 units) were achieved by daily intrathecal injections of 50,000 units and daily systemic injections of 200,000–500,000 units, while concentrations between nil and 1.5 units (average, 0.6 unit) were achieved by daily intrathecal injections of 25,000 units and daily systemic injections of 100,000 units. These findings indicate that intrathecal doses greater than 25,000 units daily may be required to combat *H. influenzae* infections. The dangers associated with this dosage are discussed.

We desire to thank Dr. W. L. Burgess, C.B.E., and Prof. W. J. Fulloch, O.B.E., for granting us facilities for the preparation of this paper, and Dr. J. Gordon, Senior Lecturer in Bacteriology, University of Leeds, for very kindly typing the organism.

ACUTE ENTERITIS IN SUBTROPICAL CLIMATES

BY

IAN MACGREGOR, M.R.C.S., L.R.C.P.

Acute enteritis in subtropical climates is the cause of the loss of a great number of working hours, and is therefore a vital consideration in industry as well as to Forces in the field. It is, in fact, responsible for the loss of many times more man-hours than are lost from intestinal diseases such as typhoid or dysentery, which, though much more common than at home, do not normally reach a serious level, except in the event of a definite epidemic.

acute enteritis. The cases included in the statistics for upper respiratory infections were attacks of acute nasal catarrh and fresh cases of sinusitis. Cases of chronic nasal catarrh and chronic sinusitis with acute exacerbations were excluded for the reason stated later. The cases of acute enteritis taken were those of simple diarrhoea—i.e., those with loose frequent motions only, with no obvious blood or mucus. Microscopical examinations were carried out on the faeces of most of these cases, and the typical pathological report was: "Loose stool; no blood, mucus, or pus seen; culture, *B. coli* only"; or "Loose stool; some mucus with an occasional pus cell seen; no blood; culture, *B. coli* only." The occasional case the report of which proved it to be a true dysentery was withdrawn from the statistical figures. Pathological examinations were not carried out on swabs from the nose and nasopharyngeal cavities in either of the two conditions, as such swabs have frequently been investigated by other workers on upper respiratory infections and the common organisms usually present are well known to all.

The incidence of the two diseases in relation to climatic conditions and diet was also studied, and the following observations were apparent.

Climate

(a) Sandstorms and khamsins appeared to cause no increase in the incidence of acute enteritis or in fresh upper respiratory infections. This observation suggests that the pathology of subtropical acute enteritis is more complex than a mere irritation of the bowel. These storms did, however, produce a marked increase in the incidence of acute exacerbations of chronic rhinitis and sinusitis. It was this fact which induced me to exclude such cases from the statistical figures, as it appeared that there must be some slight difference in the pathology involved. Other observers have stated that sandstorms and khamsins have increased the incidence of acute enteritis, but this was certainly not so in this large series of cases.

(b) Climatic conditions conducive to the common cold—such as sudden cold spells after severe heat, a sudden fall in the night temperature after a very hot day—and men who admitted going to sleep on the top of the bed in the open air without pyjamas or bed-clothing, produced not only an increased incidence of acute respiratory infections but a corresponding increase in the number of cases of acute enteritis. This was most pronounced at the beginning of a hot season, when Service dress was changed from the winter uniform to the thin summer khaki drill. The period over which these observations were

Graph showing weekly incidence of upper respiratory infections and acute enteritis in subtropical climates.

My attention was first drawn to the possibility that the cause of these cases of acute enteritis may be in some way related to the causative organism of upper respiratory infections by the fact that, while serving with the Royal Air Force in the Middle East, I kept a graph indicating the weekly incidence of these two conditions. A careful study was made of the incidence of acute enteritis as related to upper respiratory infections, and the possibility of a correlation between these diseases became apparent (see Graph)—a rise in one being accompanied by a corresponding rise in the other, and vice versa.

Over a period of 80 weeks observation was made of this relationship, and during that time the figures involved no fewer than 455 cases of upper respiratory infections and 357 cases of

made included two such occasions, and on each of them the incidence of both conditions showed a marked increase.

Diet

The observations were made at a base station in Egypt where rations arrived regularly, were always plentiful, and were more or less standardized, with only slight variations from week to week. There appeared to be no connexion between the incidence of acute enteritis and any one specific ration issue, except an occasional and obvious epidemic of acute food-poisoning that was traceable to one particular commodity in the week's issues. The recognition of such epidemics was made even easier by the fact that I was medically responsible for three

individual units, each of which drew its own rations independently of the others, so that when such an epidemic occurred it was usually confined to one camp. It was also noted that such epidemics were almost without exception accompanied by an acute gastritis.

The figures of these epidemics, too, were deleted from the statistics, as they obviously involved an independent pathology.

Discussion

The present general opinion in textbooks regarding acute enteritis must be borne clearly in mind—namely, that it is unconnected with any specific infection or disease, is caused by irritation of the bowel by sand or dust or by coarse and unsuitable food, and by exposure to chill.

If this condition was a simple irritation by sand or dust one would expect to find a marked increase in incidence during the khamsin season or following a sandstorm. In this particular series of cases such was certainly not the case. Further, one would expect to find a high incidence of associated acute gastritis; for, although the gastric mucosa is known to be much less sensitive than that of the intestines, one would expect an extraneous irritant such as sand or dust to prove sufficiently irritating to affect it. Apart from the oesophagus, the only other possible portal of entry for such irritants is the anus, the nervous control of the sphincter of which would immediately result in its contraction if stimulated by such an irritant, rendering entry most unlikely. Should entry occur by this route, however, the irritation would immediately set up peristalsis, which would prevent the irritant penetrating high into the bowel and bring about its expulsion within a very short space of time.

If the origin of the irritation was coarse or unsuitable food one would expect an increased incidence of the condition with particular food issues, and also a higher incidence of associated gastritis, but such was not the case. It was obvious, however, that when the enteritis was due to a more severe irritation—such as an extraneous poison, as seen in the cases of "food-poisoning"—the stomach was affected as well as the intestines, and an associated gastritis almost invariably resulted.

Considering the question of exposure to chill, observations show very definitely that under any conditions conducive to the common cold not only the incidence of acute enteritis is increased, but also that of upper respiratory infections. Workers in the field of paediatrics have recently inclined to the view that acute gastro-enteritis in infants is primarily due to invasion of the intestinal tract by a virus or group of viruses, and the damage to the mucous membranes thereby sustained renders them more vulnerable to the ordinary bacterial flora of that region, notably coliforms and enterococci—a view similar to that at present accepted by many authorities as the pathological explanation of the common cold. The same theory can be applied to the acute enteritis of the subtropics, and provides an explanation for the observations recorded above. The absence of an associated gastritis can be accounted for on the following grounds: (1) that the virus, in the first place, lodges in the nasopharyngeal cavity and reaches the intestines by invasion of the blood stream—a process proved to occur in certain other diseases; (2) that the virus gains direct entry to the intestinal tract from the nasopharynx through the oesophagus, the slightly higher resistance of the adult gastric mucosa being sufficient to protect it from damage by the virus as it passes through this organ; or (3) that, the bacterial flora of the adult stomach being different from that of the small bowel by reason of the high pH value of its contents, there are not the organisms to attack the mucosa when it has been damaged.

Conclusion

These observations suggest that the pathology of acute enteritis as it occurs in subtropical climates is more complex than that resulting from irritation by sand, dust, or coarse unsuitable food, and that the resistance of the intestinal mucosa is lowered either by chill or by the invasion of an unknown virus or group of viruses, rendering it vulnerable to the bacterial flora of that region.

OVERDOSAGE WITH BROMIDES

A REPORT ON 59 CASES

BY

E. CUNNINGHAM DAX, M.B., B.Sc., D.P.M.

Medical Superintendent, Netherne Hospital, Coulsdon

Bromides are still very widely used, often as a placebo in patients with a psychoneurosis. It appears that the danger associated with their prolonged administration have not been sufficiently stressed, although there have been a number of articles written on the subject (Pilkington, 1941; Kitchin, 1942; Barbour *et al.*, 1936).

Bromides given in so small a dosage as 10 gr. (0.65 g.) thrice daily can sometimes produce a state of intoxication in an elderly patient within a few weeks. The amount of bromide in the blood appears to affect patients differently, probably according to their renal efficiency. In arteriosclerotic patients a blood bromide of 125 mg. per 100 ml. may result in signs of overdosage (the normal is less than 25 mg.), whereas young epileptics with a blood bromide of twice this figure have been seen apparently free from physical signs attributable to the drug. The present extensive use of bromides is hard to justify for they are poor hypnotics and not very good sedatives. Sodium amytal 1 gr. (65 mg.) three times daily in acute cases of anxiety, or phenobarbitone 1/2–1 gr. (32–65 mg.) morning and night for the less upset and for the more elderly patients are examples of much better sedatives.

The figures given in this paper were the result of the routine blood bromide estimations on 1,500 patients in a little over two years. The first 800 were continuous, and the last 700 were made on unselected cases, but owing to absence of a laboratory staff there were gaps in the continuity. Many of the figures for the bromide estimations are low, as it was often three to seven days after admission before estimation could be made, while many of the cases had previously been in the observation ward for about the same period before admission.

Incidence of Raised Blood Bromide

A blood bromide of 125 mg. per 100 ml. or over was present in 4% of admissions, and the very wide use of these drugs reflected in the 34% of admissions in which the value was over 25 mg. It is interesting that Garrard (1942) found, among 1,042 consecutive admissions to the North Carolina State Hospital, that 4% had a blood bromide of 150 mg. per 100 ml. or over, and 27.5% a figure of 50 mg., the corresponding values in this series being 2.4% and 22%. The figures in this series are also very like those of Tod (1942).

The following Table shows the numbers of patients with the various levels of blood bromides found among the 1,500 admissions:

Blood Bromide in mg./100 ml.	<25 (Normal)	25–49	50–100	125	150	175	200	225	250	275 or over
No. of cases:	994	329	118	23	12	11	5	1	2	3

It will be seen that there were 59 cases with a blood bromide of 125 mg. per 100 ml. or over—that is, they were above the minimum intoxication level—and the following results are derived from an investigation of these cases.

The Table below gives the age incidence in this series of 59 compared with the total admissions to hospital in the corresponding period:

Age:	<25	25–34	35–44	45–54	55–64	65–74	75 or over
% of cases with blood bromide of 125 mg./100 ml. or higher	7	12	20	24	20	12	1
% of total admissions to hospital in these age groups	13	17	19	16	14	11	5

The expected increase in high bromide values with age is as well shown as might be anticipated.

Physical State and Bromide Intoxication

The rash is rarely found in cases of bromide intoxication, since it is usually an early sign of intolerance. In this series a pustular rash was seen in 3 patients.

Neurological signs are often found as evidence of bromide intoxication, and 20 of the 59 patients showed some abnormalities. In 12 there were ocular signs such as sluggish, unequal, or irregular pupils, nystagmus, or ptosis; in a further 8 there was ataxia, headache, slurred speech, weakness, or retention of urine.

Anorexia is not infrequent, and a condition is sometimes seen in bromide intoxication in which there are signs suggesting a likeness both to general paralysis and to disseminated sclerosis. This is probably a reflection of a vitamin B lack, as may, for instance, be the somewhat similar alcoholic pseudo-paralysis. During their stay in hospital 4 of the patients lost more than 7 lb. (3.17 kg.) in weight, 11 gained more than 7 lb., 8 gained over 14 lb. (6.35 kg.), 1 gained 2 stones (12.7 kg.), and 2 gained more than 3 stones (19.05 kg.).

Physical illness was common among the patients with high blood bromide readings: 5 had some cardiac insufficiency, 2 chronic bronchitis, 2 a cerebral thrombosis, 2 were recovering from pneumonia, while other conditions found were pernicious anaemia, duodenal ulcer with secondary anaemia, a carcinoma of the oesophagus, and migraine. Six patients were seriously ill on admission, their blood bromides being 300, 300, 200, 150, 150, 125. The subsequent improvement of 5 suggests that, at least in part, their serious state was due to this cause. It was likely that the bromides contributed to the death of the sixth patient; this has previously been suggested in other cases (Pentreath and Dax, 1937; Kitching, 1942).

Among the 59 patients there were 7 deaths within a year of admission. Albumin was found in the urine in 8 of the 56 cases in which records of urine testing are available. No fewer than 5 of the 7 deaths occurred among these 8 cases. In 12 patients there was gross thickening of the peripheral arteries, and 10 of the 47 in whom the blood pressure was recorded had a diastolic reading of over 100 mm. Hg. The blood urea was estimated in only 13 of the cases; in 6 the reading was between 40 and 50 mg. per 100 ml., and in one it was 196 mg.; the remaining readings were under 40 mg.

In 19 of the 59 cases the blood sedimentation rate was greater than 8 and 16 mm. with a 200-mm. Westergren column. In 4 of the 19 no satisfactory explanation was discovered, but there did not appear from the present series of figures that there was any proper evidence to support a relationship between a high blood bromide and a raised sedimentation rate.

Mental State

The following Table illustrates the various psychiatric illnesses from which the patients suffered on admission:

	No. of Cases
Senile and arteriosclerotic dementia	15
Psychoneuroses	12
Depressive states	12
Schizophrenia	6
Paraphrenia	5
Mania	2
Epilepsy	2
Other conditions	5

It appears that the symptoms in 13 of the cases were largely due to the bromides. Some special form of psychiatric treatment was required by 26 of the 59 before discharge, in 17 electrical convulsion therapy was given, 4 had insulin comas, and 2 modified insulin shock therapy. Sensenbach (1944) lists confusion as the commonest symptom; it was found in 18 of his 49 cases, and 15 were in stupor. Of the present series 14 showed much confusion but only 2 were stuporous.

Treatment

When the blood bromide is 100 mg. per 100 ml. or higher the usual treatment is to give common salt by the mouth in beef-tea or with sugared cordials; in this way 2 or 3 drachms (8-12 g.) of salt can easily be given in a day. If the blood bromide is over 200 mg. it is usual to give rectal salines in addition, while intravenous salines have been used on a number of occasions. Vitamins are always added to the diet in these cases. In most instances the blood bromide becomes normal in about two to three weeks, but in 2 of these patients it changed

very little in the first month. Improvement in the mental state may lag behind the elimination of the bromides even though it is induced by their use.

Of the 59 cases with high blood bromides, 46 were discharged, 7 died, and 6 remain in hospital. The length of stay in hospital is shown in the following Table:

Time in Months:	<1	1-3	3-5	5-7	>7
Number of patients	4	18	13	4	7

In conclusion, it may be stressed that a number of the symptoms for which bromide is often prescribed may actually result from the drug itself; therefore an increase in dosage should be avoided if the condition becomes worse. It is unfortunate that the teaching in regard to the therapeutic uses of bromides, and in particular for the treatment of epilepsy, has lagged behind clinical knowledge. As bromides are easily obtained, a number of cases of self-intoxication arise; 7 of the 59 in this series occurred in this way. It is therefore important to be prepared to treat these cases as well as to guard against their causation.

Summary

Not only are bromides of less therapeutic value than their wide use would indicate, but they are dangerous drugs to use on certain patients.

Their prolonged administration, even in small doses, often produces intoxication.

Fifty-nine cases with high blood bromides have been examined.

I would like to thank Dr. W. A. Hulme, of the laboratory staff, for the estimations.

Medical Memoranda

Laryngeal Foreign Body

The main interest in the following case is the fact that such a small child could harbour such a large foreign body in its larynx for four months and survive.

A male child aged 11 months was admitted to a medical ward of the Belfast Hospital for Sick Children on Aug. 11, 1945, with the diagnosis of laryngismus stridulus. The mother gave the history that he had been a healthy baby until 4 months before, when he had taken "cramp" and was admitted to a provincial hospital with the diagnosis of bronchopneumonia and diphtheria. He was discharged after two weeks. Three weeks later he was readmitted as a case of rickets, and remained in hospital for 10 days. Since then he had been having sun-ray treatment, but his condition had not improved.

FIG. 1.—The foreign body.

He perspired freely and coughed up mucus and there was some vomiting. He was taking feeds (Sister Laura's food) fairly well and slept well. His chest had been x-rayed in the out-patient department, and reported normal. His temperature on admission was 99.6° F. (37.55° C.). There were extreme wasting and evidence of rickets:

his weight was 11 lb. (5 kg.). Nothing definite was noted on clinical examination of chest or abdomen. The Mantoux reaction was negative.

During the next three weeks he vomited frequently and did not take feeds well. An attempt was then made to pass an oesophageal catheter, but this failed. Three days later I was asked to see him. He was extremely wasted and appeared to have some laryngeal obstruction. The same evening I performed a direct laryngoscopy without anaesthesia. On exposing the larynx a foreign body was seen to be impacted in the larynx between the true vocal cords. After some difficulty, as the only instrument available at the moment was a pair of Mackenzie's forceps, the foreign body was removed and found to be a metal rivet 1/2 in. (1.27 cm.) long, the base having a diameter of 1/2 in. (Fig. 1). There was no evidence of

FIG. 2.—Skiagram showing the foreign body impacted in the larynx.

oedema following the manipulation, and the child improved at once. He was discharged 10 days later, having gained 2 lb. (0.9 kg.).

After the child had been discharged it struck me that the skiagram of the chest would include the larynx in such a small subject. The plate was obtained, and the foreign body was plainly visible (Fig. 2). It may have been seen in the first place and thought to be something in the child's clothing.

I wish to thank Dr. Rowland Hill for permission to publish this case.

KENNEDY HUNTER, M.B., B.Ch., F.R.C.S.Ed., D.L.O.

Lingual-nerve Block for Calculi in Wharton's Duct

A patient was seen with a large calculus impacted near the orifice of Wharton's duct. The lingual nerve is the only sensory nerve of the floor of the mouth between the midline of the tongue and the alveolar margin, and it occurred to me that a block of this nerve would meet the analgesic needs for the removal of a calculus in the oral part of this duct. I blocked the nerve, and an ideal analgesia resulted. The calculus was removed without discomfort to the patient. This was in sharp contrast to my previous experiences with surface and local infiltration analgesias. The former is inadequate, and the latter requires the calculus and the anatomy. Neither is satisfactory. ordinary textbooks do not mention the use of lingual-nerve block for this commonplace minor operation, nor are my colleagues acquainted with it; therefore this short note may be of interest.

TECHNIQUE

The internal oblique line of the mandible is a sharp ridge of bone which descends from the coronoid process to bound the retromolar fossa medially; the pterygo-mandibular ligament is attached to it just behind the third molar tooth at an acute angle. This angle is the anterior wall of an areolar space between the ramus of the mandible and the superior constrictor of the pharynx. The lingual nerve descends in this space and is most superficially placed behind the lowest part of the angle. A finger in the retromolar fossa will identify the internal oblique line, and just medial to it is the pterygo-mandibular ligament. If the finger-nail is facing inwards it will guide the injecting needle to the lingual nerve. 2 ml. of 2% procaine with adrenaline will produce complete analgesia in five minutes.

Reviews

SOCIAL MEDICINE IN FRANCE

Les Directives de la Médecine Sociale. Médecine de Soins: Médecines Prophylaxie. By Noël Fiessinger. (Pp. 300. 230 francs.) Paris: Mass et Cie. 1945.

It is not sufficiently realized in this country how great is debt to France for her example in social legislation. pioneer work on maternity and child welfare and social insurance has usually been one step ahead of us, in conception at least if not in practice. The "Revolution of Our Times" in social matters has been progressing steadily in France since 1914, under the German occupation, and in this book, *The Code of Social Medicine*, authoritative views are expressed on some of the most important aspects of social medicine by a widely representative series of writers under the editorship of Dr. Noël Fiessinger.

Recent legislation has increased the amount and scope of social insurance, which differs chiefly from our present system in that it is a compulsory system. The State contributes correspondingly high contributions by employer and employee. Thus at present the comprehensive payment is 16% of wages, of which the employer pays 10% and the employee 6%.

In the medical service, which corresponds to our National Health Insurance scheme, the upper income limit for participation is 60,000 francs per annum. The patient and his dependants are insured. They have free choice of an approved society, although apparently some pressure is exerted by big firms for their workers to join the firms' mutual benefit societies. As regards doctors the patient is given a free choice, and he may consult any doctor at any time. He pays his fee "on the spot" on a fixed scale for the consultation or treatment, and the doctor signs his insurance card as a receipt. The patient gets the fee returned on presentation of the signed card to his society. The benefits, in addition to a general practitioner service, include provision for antenatal care, home or hospital care at time of delivery, sickness benefits, and pensions for invalidism—the last for the insured himself only. The patient has free choice of a hospital and his society pays 80% of the cost, the remainder being found by the patient.

The medical service is in process of change, and there is evolving a system of centres for general practitioner consultation with a central clinic to which cases are sent for specialist consultations. The Assistance Médicale Gratuite seems to be organized very much as in this country. The responsible department is the local authority, and patients may go to any doctor on an approved list. The local *maire* keeps a list of those entitled to free medical attention. All ex-Service men are entitled to free medical attention and have free choice of doctor. A new corps of medical inspectors of factories was formed in 1941, and is developing into a complete Industrial Medical Service whose organization might well be studied in this country before the omissions from Mr. Bevan's proposals are remedied.

The progressive "socialization" of the profession in France is well illustrated by the passing of the "conseils de l'ordre." These local bodies which governed professional conduct in all professions have had their names changed (for that would appear to be the sum of it) to "syndicats." The change might be described as from a "trade guild" to a "trade union."

We have not heard much from our French colleagues during recent stormy years, and this book is a useful reminder that we should do well to avoid complacency in our own institutions until we have more detailed knowledge of progress made in France and other countries.

PSYCHIATRY IN MODERN WARFARE

Psychiatry in Modern Warfare. By Edward A. Strecker, M.D., Litt.D., LL.D., and Kenneth E. Appel, M.D., Sc.D. (Pp. 88. 6s.) New York: The Macmillan Company.

This is a short but very interesting and important book. Two psychiatrists of great experience who have served in both world wars sum up their conclusions, first on the nature and incidence of psychiatric conditions and secondly on the difficulties and requirements of demobilization and rehabilitation. It would

appear that the lessons of World War I were not applied as they ought to have been in the United States either in selection of recruiting or in establishing sufficient personnel to deal with psychiatric casualties which have been not only actually but relatively higher in World War II. This the authors attribute to the greater terror of modern warfare and also to greater calls for adjustment to climatic and other conditions arising in tropical and arctic warfare.

In the recent war there has been more anxiety and less hysteria, and fear has been more exclusively the emotion underlying conflicts. The most striking feature has been the large incidence of psychosomatic troubles, though this may have been due to their more ready recognition, but the manifestations have been much more commonly in the digestive system than in the circulatory system, which loomed so largely among the invaliding disabilities of the first war.

In the second part the authors stress the difficulties now confronting the returned soldier and his family, his employers and his community, in the process of readjustment, which call for real understanding and patience and not sentimentality and stereotyped methods. They sound a note of warning on the very large numbers of men who have been discharged for psychiatric conditions and the inadequacy of the provisions to meet the need. No one should grudge the time spent on this little book of 88 pages; readers will be richly rewarded in interest while their ideas and social consciences will certainly be stimulated.

ATLAS OF DERMATOLOGY

An Atlas of the Commoner Skin Diseases. By Henry C. G. Semon, D.M., F.R.C.P. Third edition. (Pp. 343; with 139 plates reproduced by direct colour photography from the living subject. Photography under the direction of Arnold Moritz, M.B. 50s.) Bristol: John Wright and Sons. 1946.

This deservedly popular atlas of dermatology has now reached a third edition. Although, as the author states in the preface, no atlas can take the place of a standard textbook, and still less can it serve as a satisfactory substitute for actual clinical inspection of cases, it is extremely useful both to the student and to the teacher of dermatology. In particular the practitioner to whom the facilities of a large dermatological clinic are not readily available will find it very helpful when confronted with a puzzling manifestation of skin disease (and there are many such) and he may thereby have a much better chance of arriving at a correct diagnosis, while the specialist teacher at whose feet a class of students cluster will find his powers of exposition greatly aided by having this atlas available so that he can show them pictures to compare and to contrast with the clinical conditions actually before them.

The photography in the present volume reaches the high level which the former editions would lead us to expect, and perhaps Plate CXVIII—necrobiosis lipidica, specially mentioned by the author in his preface—is outstanding as a representation of a condition very difficult to render in a lifelike manner. But we must add that in a few instances the colour values do not seem quite correct, the reds are too purple; and why in the plate of naevus verrucosus (LXXVIII) is the hair dyed green? But anyone who has attempted colour photography will not withhold sympathy, for the difficulties in obtaining lifelike colouring are immense, and for the most part they have been successfully overcome in this atlas. We again recommend it to the profession.

HAPPINESS IN MARRIAGE

Marriage and Freedom. By Dr. Eustace Chesser. (Pp. 149. 12s. 6d.) London: Rich and Cowan Medical Publications.

The author is one of those who have studied and written about the question of sex education for children, a subject the importance of which the Government has now openly recognized. Too often, however, sex education has been confined to the physiological facts of life and has meant no more than an anatomical, physiological, and sometimes pathological disquisition on coitus. While no one can doubt that the fog of ignorance and prejudice which surrounds the subject of physical union is thoroughly bad for society and the future of the race, and that without enlightenment of young people marriage can hardly be expected to be successful, there is "more to matrimony" than mating and child-bearing. In this book, while the physical aspects still loom largely, the author has endeav-

oured to touch on the wider questions of the economic and social background. Marriage should be a companionship in every sense of the word except, according to the author, that of the trial trips called companionate marriage advocated by Judge Lindsey. The wife has a right to an equal status and freedom in every aspect. She should be enabled to get full enjoyment of the physical union, and this will depend on the patience, understanding, and skill of the husband. She should be free to enjoy the company of her own friends and free to manage her own share of the family income, and in all these respects the husband, of course, should be equally free. But, as has often been said, freedom is not licence, and can only be enjoyed with a full sense of responsibility and a measure of self-control which is, to say the least of it, difficult for most people.

What is wanted to bring about happiness in marriage is knowledge, tolerance, and clear thinking, and these are specially necessary for ministers of religion, who ought to be, but too often are not, the helpful advisers of young people about to marry. All these matters the author discusses in simple language, and his book may well serve as an introduction to that wider sex education which is so necessary for human happiness.

Notes on Books

The Mentally Ill in America, by ALBERT DEUTSCH, is published in New York (Columbia University Press) at \$4, and in London by the Oxford University Press at 26s. 6d. The author has produced a painstaking and illuminating history of psychiatry in America. Naturally it will be of greatest interest to Americans, but it will repay study in this country because of the continuous close association between the social and cultural institutions of the two nations which still pertains to-day, especially in medicine. The first chapter is devoted to the theories of demoniac possession which were held by the ancients, after which an exposé is given of the astonishing cruelties, prejudices, and superstitions which marked the treatment of the mentally afflicted in the 17th and 18th centuries. A good historical survey follows of the dawn of light due to Pinel and Tuke in Europe and Benjamin Rush in America. Real progress, however, had to await the foundation of the mental hygiene movement by Clifford Beers and the work of such men as Adolf Meyer, Healy, and many others. Meanwhile the public conscience had been roused by the accounts of the terrible conditions in the asylums given by Dorothea Lynde Dix. Chapters on the progress of American medical and social provision for mental deficits and on the relation of psychiatry to the criminal law are of great interest. Finally, the future trends of mental hygiene are outlined and Dr. Deutsch rightly points out that it is not only the individual patient who must be considered but the social milieu in which he has to live. Until mankind can construct a world in which the "four freedoms" really pertain we cannot expect much real improvement in the mental health of the community.

The librarian of the Royal Medico-Psychological Association should properly be at once an expert in diseases of the mind and a connoisseur of literature, and in *Analecta Psychiatrica* (H. K. Lewis and Co.; 16s.) Dr. J. R. WHITWELL shows how well he fits this dual role. In the first part he presents to us his collection of quotations relating to mental disorders which he has culled from the whole gamut of literature from Plato to the moderns. In the second part he gives brief notes on historical personages who were mentally afflicted in one way or another. As a bedside book for the psychiatrist this could hardly be bettered, and those who like to illuminate their own writings with "tags" from the work of their forebears will here find a rich store from which to draw.

We welcome a second edition of *Psycho-Analysis and its Derivatives*, by Dr. H. CRICHTON-MILLER (Oxford University Press; 3s. 6d.). Since the time of its first appearance knowledge of the whole subject has become much more widely diffused, and therefore popular interest may be more concerned with the chapters which criticize and compare than with the brief lucid descriptions of the teachings of Freud, Jung, and Adler which were once so valuable. Especially may we commend the attention of readers to the exposition of the work of Prinzhorn, too little known in this country, which puts the whole subject on a much wider philosophical basis and with a due sense of values. In the appendices are notes on the more recent advances, including methods of shortening treatment such as narcoanalysis and Steckel's method of "direct attack." It is pointed out that the success of convulsion therapy in certain psychoses makes it highly improbable that these conditions are wholly psychogenic. In addition there are appreciative memoirs of ten distinguished medical psychologists who have died since the publication of the first edition.

Nova et Vetera

JOSEPH-IGNACE GUILLOTIN (1738-1814)

Physician and Reformer

It is singularly unfortunate that this worthy physician is remembered for his suggestion that judicial execution should be accomplished by mechanical means, while his humanitarian writings and actions are forgotten. Even numerous biographical notices, though making clear that his name was wrongly given to the guillotine, barely mention his medical career during the revolutionary terror or his valuable reports on vaccination and other medical matters.

Guillotin was born at Saintes, was educated in a Jesuit school, joined the Order and taught for some time in the Irish Jesuits' High School in Bordeaux. He then decided to leave the Order and in 1763 began to study medicine in Paris, but took his degree in Rheims on Jan. 7, 1768. In February of the same year he obtained a scholarship and was granted a professorship in the Medical Faculty in Paris; this he held from 1778 to 1783. In 1784 the King appointed a Commission to investigate the claims of Charles Deslon (1750-86), a practitioner of mesmerism who had many supporters at Court. On this committee were Benjamin Franklin (1706-90), Antoine Laurent Lavoisier (1743-94), Sylvain Bailly (1756-93), and several other scientists. Guillotin was consulted and apparently helped to draft the report, but did not sign it. The Commission concluded that no magnetic fluid could be detected in the famous tub.

Guillotin wrote: *Pétition des citoyens domiciliés à Paris* (Paris: Clousier, 1788); in this he appealed to the King to grant representation to the Third Estate in proportion to their numbers—which was allowed. He was then elected to the National Assembly, which in October, 1789, discussed various penal reforms; Guillotin took an active part in these debates, in the course of which he pleaded that death sentences should be equalized and carried out by means of decapitation through mechanical means. It must be explained that at the time commoners sentenced to death were hanged, while noblemen had their heads cut off. On Dec. 1, 1789, carried away by his zeal for reform, Guillotin expressed himself thus: "Avec ma machine je vous fais sauter la tête en un clin d'œil et vous ne souffrez pas." This remark was received by the Assembly with loud laughter, but it can be said that mechanical means for judicial decapitation had been known and employed in England, Scotland, Germany, and Italy for centuries; so that Guillotin was not proposing a novelty. It was not until June 3, 1791, that this suggestion was considered, and in May, 1792, the advice of a surgeon, Antoine Louis (1723-92), was obtained, who designed a diagonal edge for the falling knife. Next, the estimate of a carpenter named Guedon proved far too expensive—5,660 livres; so a tender for 820 livres of a German musical instrument maker, Tobias Schmidt, was accepted. Schmidt was a friend of the executioner Henri Sanson fils (1767-1840), both being violinists.

The contrivance, when first constructed, was called *la Louison* or *la Louissette*, and was tested on sheep and five dead bodies. On April 25, 1792, it beheaded a highway robber, Nicolas eques Pelletier; then on Aug. 21, 1792, the first political victim was executed, Louis David Collinot d'Augremont. The guillotine functioned daily in Paris from April, 1793, to 10 Thermidor II and year=July 28, 1794; during this time 2,625 persons were beheaded. History books mention far larger numbers, but the total would include provincial towns, where revolutionary tribunals also sentenced political suspects to death. The name "guillotine" soon became popular as the outcome of a song in the royalist journal *Les Actes des Apôtres* No. 10—though Dr. Guillotin was far from being flattered by the attribution.

In the National Assembly, Guillotin sat on a Comité de Salubrité, the secretary of which was Jean Gabriel Gallot (1743-94); here Guillotin was steadfast in his support of sound medicine and sensible hygiene; he adopted many of the proposals made by Félix Vicq d'Azyr (1748-94) and suggested that all matters pertaining to the prevention of disease in man and animals should be controlled by a Conseil de Santé; that examinations in four principal medical schools should be in

French; that surgeons should complete their studies in a medical faculty and the diploma should entitle them to practice medicine and surgery everywhere in France; that children should receive physical training. *Projet de décret sur l'enseignement et exercice de l'art guérir, etc.* (Paris: Imp. Nat. 1791).

In August, 1792, the Legislative Assembly abolished "privileged associations"; these included academies, universities, faculties, and learned societies, since republican zeal decided that medicine was an aristocratic profession, that physicians were charlatans, and that the Revolution provided the true path to liberty, equality, and fraternity. It must be admitted that these destructive decisions received the support of men with a medical education, like Marc Antoine Baudet, François Bousquet, Dr. Choffinal, Jean Baptiste Bô (1753-1811), a Ferdinand and Pierre Guillemardet (1765-1809). The physician Re Georges Gastellier (1741-1821), who tried to protest, would have gone to the scaffold had he not been saved by the timely death of Robespierre on July 28, 1794. These revolutionary decrees were not popular and the people soon asked for hospital treatment; and from the end of 1793 onwards eminent medical men like Jacques René Tenon (1724-1816), undertook to reorganize the hospital system after its chaotic disarrangement by the Legislative Assembly. In December, 1793, Antoine François Fourcroy (1755-1809) succeeded in reopening the medical schools of Paris, Montpellier, and Strasbourg. In October, 1794, Guillotin was arrested while attending the poor in the Paris market district, accused of having refused to reveal the whereabouts of émigrés. It is not astonishing that he was suspected because he continued powdering his hair and wearing breeches or *culottes* during the Terror; he was, however, soon released.

Guillotin did not publish any scientific writings, but prepared several reports in which he advocated the adoption of Jenner's vaccination in France. The famous *Inquiry into the Causes and Effects of the variolae vaccinae, etc.*, appeared in June, 1794, and soon after Pinel attempted to vaccinate with lymph brought over by Colladon—these attempts were so clumsily performed that no result was obtained. Then the Duke of La Rochefoucauld-Liancourt, with the support of Guillotin, proposed the formation of a society for the study of vaccination, and Louis Husson offered to perform vaccination gratis. Hallé reported favourably on vaccination on March 14, 1803.

In 1804 Guillotin was one of the founders of the reconstituted Académie de Médecine, becoming its president in 1807. This body was not the direct forerunner of the present-day French Academy of Medicine. It can be mentioned that a prolonged discussion took place whether beheading by a falling knife was painless, in which Thomas Sömmerring (1755-1830), Melchior Adam Weicart (1742-1803), and others took part. Jean Baptiste Sue (1760-1830) wrote: *Opinion sur le supplice de la guillotine et sur la douleur qui survit à la décollation* (Paris, 1796), asserting that the method was painful. This was denied by Jean Baptiste Leveillé (1769-1829), Georges Cabanis (1757-1808), and others, who examined severed heads as they fell into the basket.

Guillotin developed an anthrax pustule on his left shoulder of which he died on March 26, 1814. During the troublous times through which he lived it was no mean achievement to preserve an even temper and equable mind, to attempt to promote reform and introduce improvements by peaceful means, and to practise medicine according to sound principles. All this was accomplished by Joseph-Ignace Guillotin, and those who appreciate his merits will recognize in him a worthy son of Hippocrates.

H. P. B.

It is estimated that, as every twenty-fifth Swedish man or woman, or more than 250,000 individuals, suffer from rheumatic diseases, they cost the country annually well over 150 million kronor (£8,800,000) and the loss of 20 million working days. With the aim of intensifying the fight against this group of diseases a National Anti-Rheumatism Union was recently instituted, backed by a large number of big Swedish organizations, such as the Swedish Co-operative Wholesale Society, the Federation of Swedish Trade Unions, the Employers' Association, the Swedish Agricultural Federation, etc. The organization will carry on an "information campaign" for making the people more generally aware of the nature and serious consequences of rheumatism, collect funds for supporting medical research, etc. It is the intention to work largely along the same lines as a similar Danish organization, which at present comprises 125,000 members.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 17 1946

BERYLLIUM POISONING

beryllium was discovered in 1797, but in recent years it is become increasingly important because of the properties of its alloys. Beryllium copper resists corrosion,

non-rusting, non-sparking, and non-magnetic, and has good electrical conductivity, high strength, and astonishing fatigue-resisting powers. It is used in precision instruments, altimeters, aeroplane pipe-lines, carburettors, telephone switchboards, and in aircraft production. Beryllium metal also has such remarkably valuable properties that it will doubtless receive much commercial attention. The principal ore of beryllium is beryl, and from this the beryllium oxide is extracted by processing at high temperatures with concentrated acids and fusion methods which result in the production of fume and dust. Weber and Engelhardt¹ first showed that these dusts produced lung damage in guinea-pigs, while Fabroni² coined the term "berylliosis" for this pathological condition. Fairhall and his colleagues³ in 1943, however, reported a full investigation of the toxicity of beryllium compounds in animals. They succeeded in producing experimentally both pneumonitis and dermatitis with beryllium fluoride and oxyfluoride, and certain hydrolysed beryllium salts such as the chloride and sulphate.

The earliest reports of poisoning in industrial workers come from Russia, Gelman⁴ describing a condition in which shivering and fever, similar to metal-fume fever, were followed in two days by extensive bronchio-alveolitis. This lung condition he attributed to the action of fluorine which was separated from beryllium oxyfluoride in the bronchioles and alveoli. In 1940 further observations appeared in a report on 46 cases of poisoning by Berkovits and Israel.⁵ Inhalation of beryllium fluoride was followed by fever, which subsided in a few days but was succeeded in a similar period by a second phase characterized by cough, scanty sputum, dyspnoea, temperature of 102–103° F. (38.9–39.4° C.), and cyanosis of the face and extremities. Rales were heard in the lungs, particularly at the bases. The blood showed a fall of haemoglobin and leucocytes, lymphopenia, and a raised sedimentation rate, while x-ray examination revealed many small ill-defined discrete opacities, especially in the middle and lower areas. The patient usually recovered completely in 10 days to 2 months. The beryllium fluoride affected mainly the smaller bronchi which have no cartilage in their walls. These showed desquamation; their walls became infiltrated with leucocytes, and later they became blocked with inflammatory exudate, leading to minute atelectases with compen-

satory emphysema. Berkovits and Israel consider that, though resolution of the acute stage is usually complete, it may be followed by fibrosis.

Full reports of this form of poisoning are now appearing in the United States. Van Ordstrand, Hughes, and Carmody⁶ gave an account of three cases of chemical pneumonia among workers extracting beryllium oxide; and Kress and Crispell⁷ reported 4 cases of the condition in men working with fluorescent powders containing beryllium. Van Ordstrand, Hughes, DeNardi, and Carmody⁸ have now described 170 cases of poisoning which have occurred among workers in three plants during the past four years. The manifestations were dermatitis, chronic skin ulcer, and inflammatory changes in the respiratory tract, producing in extreme cases diffuse pneumonitis. The incidence and severity of the changes were proportional to the degree of exposure and were caused by the chemical irritation of dusts and fume. Acid radical salts were more toxic than other compounds, but severe damage was caused by beryllium compounds other than the acid radical salts. Contact dermatitis and skin ulcer occurred in 42 patients in contact with beryllium sulphate, fluoride, or oxyfluoride. The eruption was oedematous and papulovesicular and appeared on the exposed portions of the body, itching being intense. Inadequate cleanliness, excessive perspiration, and failure to use protective devices were contributing causes, while after exposure was terminated the condition subsided. Calamine lotion and phenol, wet packs of 10% Burrow's solution, and boric acid ointment with phenol were the more effective local treatments. The chronic skin ulcers resulted from a crystal of beryllium deposited within the skin layers. Treatment was by early incision of the papule before necrosis and curettage of the fibrous base, when healing was complete in 8 to 10 days. Conjunctivitis occurred as a "splash burn" or in association with contact dermatitis of the face. Local treatment included the use of boric acid solution with mild zinc and adrenaline.

Ninety patients were seen with infection of the upper or lower respiratory tract. Soreness of nose and throat and epistaxis were the symptoms of upper respiratory infection, and most cases cleared in three to six weeks. Lower respiratory tract infections were characterized by non-productive cough, but with occasional blood-streaked mucoid sputum and dyspnoea. Rales were characteristically present in the early phase of inspiration, fine at first but becoming coarse later. Vital capacity was reduced by as much as 30%; there was low-grade fever. If the patient was removed from contact no case of pneumonitis developed after three weeks from the onset of the bronchitis. The condition can be prevented if the workers use a face mask to stop dust entering the respiratory tract. Chemical pneumonitis developed in 38 workers, five of whom died. Symptoms were cough with occasional blood-streaked sputum, substernal burning pain, shortness of breath, cyanosis, abnormal taste, anorexia with some weight loss, and increasing fatigue. The onset was insidious, and signs were conspicuously absent. The vital capacity was reduced as low as 2,000 c.cm., but the sedimentation rate was normal.

Bronchoscopy showed a hyperaemic mucosa with some oedema. X-ray examination showed diffuse haziness of both lungs, followed by development of soft irregular areas of infiltration with prominence of pure bronchial markings, and then by absorption of the soft infiltration and the appearance of discrete large or small conglomerate nodules scattered throughout both lung fields, and finally by the clearing of the lung fields after one to four months. Necropsies showed an atypical pneumonitis; striking features in sections of lung tissue were large numbers of plasma cells, relative absence of polymorphonuclear infiltration, diffuse pulmonary oedema, and haemorrhagic extravasation; fibroblasts with evidence of organization were present. Beryllium present in the lung varied between 6.20 and 1.89 mg. per 10 g. of dry tissue.

MAN'S FRONTAL LOBES

From observations of the effects of operative removal there has been much difference of opinion on the apparent functions of the frontal lobes. Brickner,¹ in his synthesis of findings in a case in which both frontal lobes were excised in a case of tumour, concluded that the removal had caused a single basal intellectual defect, which he considered to be a loss of the power to synthesize minor thought processes into more complex structures. Goldstein and Katz² interpreted as a loss of "abstract behaviour" the results they obtained in a group of patients. Freeman and Watts,³ from observing the effect of bilateral frontal leucotomies, considered that the frontal lobes were concerned with foresight, particularly in respect to personal acts and "the relation of the self to the self." Hebb, in a useful critical review,⁴ says that, although these three general conceptions of the function of the frontal lobes differ so much, they have this in common—that they attempt to explain at once too much and too little. He points out that the theories expounded by these authors are broad and somewhat ill-defined, and that because of this it has perhaps been a little too simple to make all the observed phenomena fit into the structure of each. He is opposed to the acceptance of each of these theories, because of evidence which he has produced with Penfield⁵ from the detailed and careful observation of one case of bilateral frontal lobe amputation. In that there was little likelihood of any structural abnormality in the brain beyond the limits of the extirpation, he considers that this case differs fundamentally from those studied by other workers. The frontal lobes had been amputated because of gross antisocial behaviour associated with epileptic attacks. The abnormal behaviour had followed severe head injury, with damage to both frontal lobes and subsequent scar formation. According to Hebb there was a return to normal behaviour after complete recovery from the operation. In fact the man was able to enlist, and he was fit enough to be posted over-seas: his service was interrupted by an epileptic attack. In spite of very elaborate psychiatric observation and psychometric testing Hebb and

Penfield could find no intellectual defect as a result of almost total loss of both frontal lobes.

Hebb therefore tried to find out why his observations differed so widely from those of other workers. In analysing the differences between his case and others he considered certain general principles. To assess the effect of cortical extirpation one must be able to say how much has been removed and to be sure that no other than the operative lesion need be taken into account. Hebb points out that the neat diagrams which purport to show the path of surgical excision may be misleading. An operation is one thing; a diagram is another. No animal experiment would be complete without full anatomical data, but this can rarely be obtained in human cases. In the absence of exact knowledge of the amount and state of what is excised and what is left behind most careful alternative observations must be made: the limitations of such study must be kept in mind. Hebb says: "The moral is not to abstain from studying clinical material until the perfect case is found but to regard fallible data as fallible, to make every effort to get as good cases as possible, and to put more weight on the cases in which anatomic data are most complete and trustworthy." He also says that a negative conclusion—that a function is not dependent on a certain part of cortex—can be arrived at more accurately than a positive conclusion: it is easier to determine that an area has been removed without producing particular symptoms than that those symptoms follow destruction of one part of the cortex only. He takes the view, with which many must agree, that an adequately studied case with absence of sequelae may yield more information than another in which sequelae of uncertain cause are found. This view is important when we consider the limits of the pathological tissue in relation to the material removed, for, histologically, cerebral lesions are often found to extend much more widely than was expected, and it is also well recognized that the effects of circumscribed lesions on the function of healthy tissue may extend beyond their boundaries. Furthermore a small region of partial damage may produce more severe symptoms than a larger area of complete destruction. The electro-encephalogram shows that abnormal cerebral tissue may interfere with the function of areas of normal cerebral tissue. Hebb therefore considers that the functions of the frontal lobes can be satisfactorily investigated in cases of brain injury operated on or in cases in which cerebral tumours have been excised. And, again, as surgical intervention may cause complications in the neighbourhood of the section, that case in which the fewest symptoms follow operation is likely to be the one which gives the truest picture of the effect of the removal alone. Hebb goes on to discuss the problems raised by taking as control material persons believed to be normal. He points out that not only is it very difficult to obtain an identical group of normal control subjects in age and social and intellectual status, it is also difficult to devise an adequately comprehensive method of testing the group when it has been selected. In his view all the control material used in the past is open to criticism on these grounds.

From analysis of all the recorded cases of unilateral or bilateral amputation of the frontal lobes, Hebb agrees

¹ *The Intellectual Function of the Frontal Lobes*, New York, Macmillan, 1936.

² *Arch. Neurol. Psychiat.*, Chicago, 1937, 33, 473.

³ *Psychosurgery*, Springfield, C. C. Thomas, 1942.

⁴ *Arch. Neurol. Psychiat.*, Chicago, 1945, 54, 10.

⁵ *Ibid.*, 1940, 44, 421.

Jefferson⁶ and Lidz⁷ that there is no evidence that unilateral bectomy causes a change in behaviour. He applies this observation to the cases with bilateral amputation, backed up by the evidence provided by his own case, in which a change of abnormal behaviour could be found after lateral frontal lobe amputation.

Hebb, of course, is not so naïve as to deny function to the frontal lobes, which have their greatest development in man. All he does is to affirm that "no one has proved at any single form of normal behaviour is dependent on any part of the brain, or that a clean surgical removal of both frontal lobes has any effect on behaviour." What he has done by careful analysis of the facts at his disposal is to reach a negative conclusion. He has cleared the air for other workers. But it cannot be assumed that the frontal lobes have no effect on behaviour. Although a man seems to manage quite well in his day-to-day life without his frontal lobes, it may well be that more complex thought and behaviour, such as remote planning and initiative, capacity for adjustment or for creative work, have been seriously impaired.

ANTERIOR POLIOMYELITIS

Few infections cause as much public concern as anterior poliomyelitis. A small number of cases in a district, as, for example, in the Barnet area in the past weeks, soon give rise to parental anxiety. But, difficult as may be the problem for the general practitioner, an outbreak in a residential school constitutes an epidemiological—and a psychological—problem of the highest importance for the school doctor. A memorandum by the Medical Officers of Schools Association⁸ is therefore timely. A number of medical men with special knowledge of the subject were invited to consider the action which should be taken at a residential school on the occurrence of the disease, and their report contains valuable guidance for all who may have to face such a problem.

The memorandum opens with a short note to headmasters. It is emphasized that even in an epidemic the likelihood of a particular child's being attacked is small. One of the still imperfectly explained vagaries of this infection is that overt cases of paralytic disease are the exception. Usually 80% or 90% of those exposed show no apparent upset. Of cases reported by Illingworth,⁹ for example, about two-thirds of those attacked by the virus suffered from a mild abortive illness only, with no sequelae. The diagnosis of the single case, therefore, is not necessarily a cause for acute concern, since case-to-case infection will not as a rule be common. The committee has felt disinclined to be dogmatic on the question of school closure when only one case has appeared; at this stage insistence on a rigid code of hygiene, especially in regard to food-handling, together with the imposition of a strict quarantine for three weeks, may be all that is necessary. The parents of contacts must, of course, be informed. No objection should be offered if a parent seeks to remove his child, but steps must be taken to ensure that the child is properly quarantined at home for three weeks, out of contact with young children and adolescents. Further cases alter the picture so far as parental anxiety is concerned, and the committee advise that on this account

alone "the wisest course may then be to disperse the school for at least three weeks." The cases will have been notified to the local medical officer of health, who may supply information regarding others in the district. Close liaison with the public health department is always wise in these circumstances, and consultation between the headmaster, the school doctor, and the M.O.H. is advisable. The second part of the report contains a suggested basis for a letter from the headmaster to parents. This puts the position clearly. As has been said, no obstacle should ever be placed in the way of a parent who desires to remove his child. At the same time the parent must be warned of his responsibility to the community. The local health department of the district to which the boy is removed should be notified of the circumstances.

The Medical Officers of Schools Association has also taken this opportunity to revise that part of its "Code of Rules for the Prevention of Communicable Diseases in Schools" which deals with poliomyelitis. The importance of the gastro-intestinal as well as of the respiratory tract, both as a source of infection and in transmission, is properly stressed. It is not much of an exaggeration to say that the modern conception of the disease would place it in the same group as typhoid fever in so far as methods of control are concerned, and would emphasize the importance of food, fingers, flies, and faeces. It is perhaps still too early to assess the importance of vectors in the spread of the disease. The detection of poliomyelitis virus in faeces was reported in 1941 by Paul and his co-workers¹⁰. More recently, Ward, Melnick, and Horstmann¹¹ have supplied evidence that flies thus infected may be a link in the chain of infection. Since D.D.T. has apparently proved effective in the control of such conditions as sandfly fever, its intensive use in the face of an outbreak of poliomyelitis might seem worthy of trial.

"BENADRYL"

A substance which has anti-histamine properties is likely to have an extensive use in therapeutics, for the liberation of histamine in the tissues is believed to be an important factor in many allergic and anaphylactic phenomena. Such a substance¹² has recently been synthesized and studied, and under the trade name of "Benadryl" is now available in this country. This organic compound (B-dimethyl-aminoethyl benzhydryl ether hydrochloride) is a stable white powder, soluble in water and alcohol. It is active when taken by mouth, but may also be given intravenously to the human subject.

In experimental work on guinea-pigs it reduced the mortality from histamine shock from 100% to zero. Its clinical applications in allergic disorders have been studied by a number of workers at the Mayo Clinic.¹³ Though mild side-effects occur, it was found that there is a good margin of safety between the therapeutic dose and that required to produce toxic symptoms. When histamine is slowly injected intravenously a general cutaneous flush and nasal congestion normally result. Both these could be promptly controlled by the intravenous injection of benadryl. Usually, however, it has been taken by mouth, and in doses of 50 to 100 mg., two to five times a day, it was tried in a series of 15 cases of acute urticaria. It brought prompt relief to 9 and improvement to a further 5, with a decrease in pruritus in half to one hour and, in the successful cases, disappearance of the lesions in two to six hours. In another series of 35 cases of chronic urticaria and angio-

neurotic oedema, of duration varying from four months to thirty years, the lesions disappeared in 25, and there was improvement in a further 7 cases. Good results have also been noted in hay fever. At least 75% improvement was obtained in 19 out of 22 cases, and the relief in cases of vasomotor rhinitis was striking. Less satisfactory results are reported in bronchial asthma, though on theoretical grounds this condition would seem well suited to the use of the drug. Two-thirds of such patients have failed to benefit from adequate dosage of the drug. However, more careful selection of truly allergic cases may lead to a higher proportion of successes in this group. In certain types of headache, particularly those made worse by histamine, good results were obtained, but other types of headache responded less well.

One interesting use of benadryl was in a 3-year-old child with nephrosis who had had an urticarial reaction after every plasma infusion. When benadryl was administered both before and after a transfusion little reaction occurred. Another child developed a severe urticaria after the injection of tetanus and gas-gangrene antitoxin. This was promptly relieved by 30 mg. of benadryl orally. The side-effects which accompany its administration are usually mild, and in a series of 100 cases were never severe enough to call for discontinuance of the drug. Sleepiness was noted in 60% of cases; dizziness, dry mouth, and a feeling of nervousness each affected about 15%.

PROTECTION OF SCIENCE AND LEARNING

Thirteen years ago, at the beginning of the new era of persecution, some British scholars thought of establishing a society to alleviate suffering already foreshadowed. We do not know who was the actual pioneer, but certainly Sir William Beveridge, Prof. Charles Singer, and Prof. Major Greenwood were early in the field. In a very short time, under the title of Academic Assistance Council, a body was formed which included the most illustrious names in British science and learning; it was generously supported not only by a wealthy men and organizations but by hundreds of individuals who could ill afford a new subscription. Later, the society was renamed Society for the Protection of Science and Learning; at the outbreak of war appeals for funds and the publication of an annual report ceased. Now the society has issued an account of its work during the war.¹ In one sense this is a cheering document, for it not only records the saving of the lives and minds of several hundred gifted human beings, but shows what service they have since done for mankind in general and our cause. As was to be expected, medicine and its ancillary sciences contribute a large proportion of those the society has helped; of the 601 scholars registered with it more than one-sixth have aided this country in the medical services of the fighting Forces, in medical research, medical teaching, and clinical practice. Those who have worked for the S.P.S.L.—some of the busiest men and women in England have worked hard for it, and the devotion of the small permanent staff has been beyond praise—and those who have been generous in supporting it will read this document with comfort. Old-fashioned readers may remember "Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me." It is easy to be eloquent on the brotherhood of science and learning, better and much more difficult to help even a few of our brethren. Sorrowful people, strangers in a strange land in time of war, are not always easy to help;

that fact, painfully familiar to those who have done the society's work, leads to the less cheerful side of the report.

Every reader of newspapers knows that progress in the reconstruction of Europe is slow; it is vain to expect the restoration of those scholars and scientists who wish to return to what were their homes can be rapid; it is certain that some may not wish to return at all. It would not be possible to wind up the society quickly without making another small contribution to human suffering. Inevitably the society's present rate of expenditure exceeds its income, and these are not times when a public appeal for funds would be reasonable. Still it has generous helpers, who will continue to help after the propagandist appeal made by any organization which is certainly anti-Nazi has lost its impetus, and after an official need to secure good brains for war work has been sated. Perhaps there may even be recruits to the ranks of subscribers. The society will continue to help the men of science and humanists driven into exile by "ideologues" now dead. If funds permit it may be able to help others whose fate is, or will be, to bear the wrath of "ideologues" still living in Europe at present.

"Chaos umpire sits,
And by decision more imbroils the fray
By which he reigns; next him, high arbiter,
Chance governs all."

AUTONOMIC RESPONSES AFTER FRONTAL LEUCOTOMY

It is now fairly well established that the effects of section of the white matter in the anterior part of the frontal lobes can be of therapeutic value in some cases. Most of the patients who have benefited have suffered from chronic and severe disorders of the schizophrenic, depressive, and obsessional types. Success, however, can never be predicted with certainty. The prime reason for this is that the operation is a blind one, and the surgeon is never entirely sure which tracts have been destroyed. Our knowledge of the functions of the frontal lobes is too limited for an answer to be obtained subsequently, unless the patient comes to necropsy. Clinically, the beneficial results of the operation are seen in a lesser preoccupation with painful thoughts, delusions, or compulsions, and a placidity which has on occasion been compared to that of a vegetable. It was to be expected that this placidity would have an autonomic aspect, and support for this notion has been provided by some interesting experiments of Reitman.¹

All Reitman's subjects were schizophrenic females of the excited catatonic type, and consisted of fifteen leucotomized and ten control patients. A further three patients were tested both before and after leucotomy. Doses of prostigmine, eserine, ephedrine, and amphetamine were given of a strength to produce brisk physiological reactions in the control subjects; but their effects were found to be a rule perceptibly attenuated in the leucotomized patients. In the patients tested both before and after operation the reduction in autonomic lability was not seen until the fourth week but was fully established by the sixth. The degree of mental improvement was not associated in an absolute manner with the amount of autonomic change. These results provide obvious pointers towards further experiments along biochemical and physiological lines. But our best hopes of advance depend on the development of a satisfactory open operation to replace the present blind surgical procedure.

¹ Fifth Report (obtainable from Secretary S.P.S.L., c/o Westminster College, Cambridge).

CHEMOTHERAPY OF TUBERCULOSIS

The Harben Lectures for the year 1946 were delivered in London at the Royal Institute of Public Health and Hygiene by Dr. WILLIAM H. FELDMAN of the Mayo Foundation, University of Minnesota, U.S.A., on July 15, 16, and 17. His subject was the chemotherapy of tuberculosis, including the use of streptomycin.

Basic Considerations

Dr. Feldman began his first lecture by saying that though notable advances had been made during the past two decades in the surgical treatment and sanatorium care of the tuberculous patient, something more was desperately needed. The discovery of the high effectiveness of "sulpha" drugs in certain acute infectious diseases, such as pneumonia, and the amazing therapeutic value of penicillin, made it logical to assume that an agent effective in the treatment of tuberculosis would eventually be found. The problem was to discover a suitable substance which, while effective against the tubercle bacillus, did not have serious or irreversible poisonous effects on the patient. The possible action of a drug against the bacillus might be determined in test tubes, or by experiments on animals whereby its actual effect in an experimental tuberculous infection might be observed. Wherever possible the latter approach to this very complex problem was preferred. As a result of many experiments in recent years fairly satisfactory methods of tackling the problem had been evolved. The great obstacle, however, that still remained in the testing of new drugs was the relatively large amount of a drug necessary for an animal test, and in comparison with other and more acute diseases the long time taken to obtain definite results. After Ehrlich's epochal discovery of the value of salvarsan in the treatment of syphilis chemotherapy was hailed as the great hope in treating all infectious diseases. These hopes failed to be realized in the field of tuberculosis and in other infectious diseases. It was only after the discovery of the first "sulpha" drug in 1935, and the extremely significant observations of Fleming, Chain, and Flörey concerning penicillin, that hope was revived that a specific drug against the tubercle bacillus might be found.

The problem of chemotherapy in tuberculosis was best approached by group research. The talents of many specialists should be integrated so as to obtain the maximum co-operative results of the biochemist, the pharmacologist, the bacteriologist, the bio-physicist, the experimental pathologist, and the clinician. The efforts of all those were needed for the development of a successful form of drug treatment in tuberculosis. This exceedingly important field of investigation should have adequate support from public funds.

Evaluation of the Efficacy of Chemicals

Dr. Feldman's second lecture was concerned with an evaluation of the efficacy of sulphonamides, sulphones, and certain other chemicals in tuberculosis. The development of the modern experimental approach to this question originated from the observation that the sulpha drugs were highly potent in certain acute infectious diseases. Sulphanilamide was shown to have a limited but definitely deterrent effect on tuberculosis in guinea-pigs; but, unfortunately, none of the compounds of this character proved of any value in human tuberculosis. Another closely related group of compounds—the sulphones—proved highly potent in treating experimental tuberculosis in animals. This was of much significance because it demonstrated for the first time that the disease caused by the tubercle bacillus would respond favourably to drug treatment. Unfortunately, when the sulphone drugs were used for human tuberculosis they could not be given with safety in large enough doses to attain a similar dramatic effect. The development of safe compounds of this type, used rather extensively in the experimental form of the disease, had provided much important basic information which justified the belief that eventually a highly efficacious and non-poisonous drug of definite value in treating human tuberculosis would be found. The number of compounds yet untried or possible to be made was limitless.

The difficulties of the problem confronting the chemist or the experimentalist entering this field of research were many and formidable, but not necessarily insurmountable. If the skill, the experience, and the information acquired by chemists

during the exigencies of war were directed with like intensity to the discovery of chemical weapons against tuberculosis, it seemed highly probable that several safe and efficacious drugs would eventually be found.

Streptomycin for Tuberculosis

In his third lecture Dr. Feldman discussed the effect upon tuberculosis of antagonistic substances of microbial origin, with particular reference to streptomycin. An example of an antibiotic substance was penicillin, which had revolutionized the treatment of many infectious diseases; but penicillin was ineffective against the tubercle bacillus. The search for an agent derived from other microbes began nearly half a century ago and many agents of this kind had been investigated. While most of the studies had been conducted in test tubes, a few of the substances extracted were tried on human beings afflicted with tuberculosis. Until recently, however, when Dr. Waksman of New Brunswick discovered streptomycin, no substance had been discovered which was highly potent against the experimental form of tuberculosis and could also be used safely in man.

In the experimental animal streptomycin had so far proved to be the most efficacious drug for suppressing the infection caused by the tubercle bacillus. Tuberculosis in man and tuberculosis in animals had distinctly different characteristics. The disease in animals was relatively simple in character and fairly predictable in its course; in the human being the disease was far more complex, and one must therefore be very cautious in assuming that a drug effective in the experimental animal would act to a similar degree in man. A limited number of human cases of tuberculosis had been treated with streptomycin, and while in no instance had the results been spectacular they were for the most part highly encouraging. It was of great importance, however, to emphasize that the tuberculous patient must not refuse or delay conventional forms of treatment in favour of some inadequately tried drug that had shown promise in preliminary trials. While the experimental results with streptomycin up to now were suggestive of the future possibilities of this new drug the facts available did not warrant the conclusion that an ideal drug for treating clinical tuberculosis had been found.

Streptomycin was difficult to prepare and the available supply exceedingly small. It would probably be many months before there were amounts sufficient for extensive clinical investigation. This drug, however, had many virtues over previously tried substances in the treatment of tuberculosis, and it was a reasonable expectation that it would eventually find a useful place in medicine. Of much importance was the fact that the tubercle bacillus, like the germs of pneumonia, was definitely vulnerable to the suppressive action of specific drugs. This observation gave considerable impetus for investigators all over the world to search for other and more effective substances, either derived synthetically from chemicals or obtained from microbes in a manner similar to that which produced penicillin and streptomycin.

BEIT MEMORIAL FELLOWSHIPS

The following elections have been made:

Fourth-year Fellowships.—G. J. Popjak, M.D.: to study the behaviour of plasma lipids under different experimental conditions and the problem of foetal fat metabolism; at the Department of Pathology, St. Thomas's Hospital, London. Ethel G. Teece, Ph.D.: to study the chemistry of bacterial polysaccharides and nucleoproteins, with special reference to the Gram complex and to the factors responsible for cell division; at the Department of Chemistry, University of Birmingham.

Junior Fellowships.—S. E. Dicker, M.D., Ph.D.: to study the extrarenal water metabolism and renal function in rats; at the Department of Pharmacology, University of Bristol. P. M. Tow, M.B., B.S.: to study prefrontal leucotomy and the function of the frontal area; at Research Department, Runwell Hospital for Nervous and Mental Diseases.

Major-Gen. Walker, Deputy Director, Medical Services, Scottish Command, recently unveiled in Newbattle Parish Church a stained glass window in honour of the Royal Army Medical Corps, who regularly worshipped there when Newbattle Abbey was their headquarters. The window was designed by Mr. William Wilson, A.R.S.A.

Reports of Societies

POST-WAR CONFERENCE ON NUTRITION

A conference arranged by the Nutrition Society, under the auspices of the British Council, was held at the London School of Hygiene and Tropical Medicine on July 5, 6, and 8. The object was to enable research workers in ex-occupied territories to re-establish contact with their colleagues in this country. British nutritionists were thus given the opportunity to learn about dietary conditions and investigations carried out during the war period on the Continent, while the Continental workers were told about the progress of research in Britain and America.

Sir JOSEPH BARCROFT took the chair at the introductory session, when Prof. J. R. MARRACK gave a comprehensive account of wartime research on human nutrition in this country, while Dr. D. P. CUTHBERTSON dealt similarly with animal nutrition. Sir EDWARD MELLANBY spoke on the activities of the Medical Research Council; Prof. R. A. PETERS described the activities of the Accessory Food Factors Committee, Sir JACK DRUMMOND those of the Ministry of Food, and Dr. H. E. MAGEE those of the Ministry of Health.

The Scandinavian Zone

Dr. HAMMOND presided at the first open session, and Prof. FRIDERICIA, of Denmark, was the first speaker. He explained that his country normally imported calories in the form of cereals, and exported animal protein and fats in the form of bacon and dairy products. During the war less butter and sugar had been consumed, but there had been no serious privation. The usual form of bread had always been 100% rye, so that arguments about increasing the extraction rate had not arisen. The daily ration of bread for ordinary persons was 250 g., and about 70 g. of wheat flour of 80% extraction was also consumed. Among other scientific investigations in Denmark Prof. Fridericia mentioned those on the anti-haemorrhagic vitamin K, which gained a Nobel prize for Prof. Henrik Dam. On the whole the Germans did not interfere much with research.

Dr. J. K. TIKKA said that in Finland nutritional conditions remained fairly good until 1941, when scarcity of labour, infertility of the soil, and loss of territory began to take effect. Even under these handicaps country dwellers continued to get what food they wanted from the farmers through the black market. Many industrial workers and intellectuals living in towns with large families, however, had to subsist mainly on bread and potatoes with only minute amounts of milk, meat, and dairy products. In adults losses of 10% body weight were common, while in children the incidence of rickets increased.

I. O. GALTUNG HANSEN told how the food situation in Norway deteriorated until in 1940 coffee, tea, eggs, and fruit had practically disappeared. Shortage of meat was met by increasing the daily consumption of fish from 100 g. to 300 g. per person. Adults lost weight, and in some cases developed oedema. Almost everyone felt cold, tired, and weak. Hunger persisted even after meals, and nycturia was often an additional trial. The children suffered little until 1943, but then became paler, thinner, and less muscular. In the general population the incidence of infectious diseases increased six times, and notifications of tuberculosis went up by 34%.

Prof. E. L. ABRAMSON reported the results of a dietary survey of 500 Swedish families. Although during the war the consumption of meat fell to 75% of the previous level, there was little evidence of malnutrition and the death rate in 1942 was at its lowest level. To avoid the risk of vitamin A deficiency carotene was extracted from carrots and incorporated in the margarine supply.

Poland, Batavia, America

Dr. A. SZCZYGIEL, of Poland, started the second open session, at which Dr. D. P. CUTHBERTSON was chairman, with a story of tragic suffering and acute starvation. In 1941 the common

diet provided only about 1,200 calories per head, and black market did valiant service in distributing food which would otherwise have been requisitioned by the Germans. Available foodstuffs were not only inadequate in amount but were usually of most inferior quality, and were often infected with *Salmonella* or *Trichomonas*. Diarrhoea was common. The rye bread, with 25% added bran, contained a high proportion of fibre and was often sour. Nervous lesions were frequent, whilst scurvy was sometimes so severe as to cause loss of teeth. Over a million people suffered from tuberculosis, and resistance to typhus was reduced. In concentration camps 75% of the Jewish prisoners had oedema and in the ghettos infants died of hunger. Even now the food shortage in Poland was severe, and the infantile mortality remained at about twice the pre-war figure.

Dr. S. K. KON, of Reading, mentioned that he had seen a report describing the shocking effects of starvation in the Warsaw ghetto which had been drawn up by twenty-five doctors, of whom only one now survived. Prof. VAN VLIET related his experiences in Java. Confiscation of food by the Japanese was probably responsible for the death of three out of four million Indonesians.

Dr. C. G. KING, scientific director of Nutrition Foundation Inc., the large research fund financed by American food firms, welcomed the presence in Washington of Sir J. BOYD (Director-General of the F.A.O.). He said that there had been practically no nutritional diseases in the U.S.A., although the intakes of some nutrients might occasionally have been below the optimal level. Research had covered a wide range, including diets for hot and cold climates, food preservation, dehydration, human requirements for amino acids, and rehabilitation of subjects who had suffered severe loss of weight from prolonged partial starvation. He had great hopes that the work of Spies and others would lead to the successful treatment of many forms of anaemia with folic acid, which had recently been synthesized. His account of the feeding of troops in the Pacific war area by means of mobile factories which were landed complete and started ploughing a few hours after the islands had been cleared of Japanese by the assault parties, was an excellent illustration of the American gift organization.

Belgium, France, Holland, Switzerland

Prof. E. BIGWOOD, of Belgium, spoke first in the third open session, at which Dr. L. J. HARRIS presided. He said the lowest intake had been in 1943, when urban inhabitants had received about 1,800 calories, excluding those derived from milk and green vegetables. Home-produced protein fell during the war to about half the pre-war level, and in 1941 there were many cases of oedema. The increased consumption of herrings from the North Sea caused a steady decline in this condition and by 1944 cases had become very rare.

Dr. TRÉMOIÈRES, of France, said that the nutritional conditions in the agricultural districts were good, but in industrial towns the diet was often very poor. The infant mortality rate and the incidence of tuberculosis were greatly increased. Deficiency of vitamin A was suspected in groups of the population who were too poor to resort to the black market; and in some instances there appeared to be reduced efficiency in the conversion of carotene to vitamin A.

Prof. B. C. P. JANSEN told how in Holland 66% of the pastures had been used for growing potatoes. In view of the great importance of this foodstuff experiments were carried out to determine the effects of variety and season on the concentrations of vitamins C and B₁. While 30–40 mg. of ascorbic acid was found just after harvesting, only 5–10 mg. remained in storage until the following spring. One third of the daily requirement of vitamin B₁ was derived from potatoes. Holland did not suffer from severe malnutrition until 1944, when a great railway strike caused a reduction in the food intake to 500 calories daily, resulting in 20,000 deaths from starvation. Speaking of fundamental research, Prof. Jansen stated that vaccenic acid, which is present in butter fat, had been found to act as a growth factor in rats.

Prof. D. F. VERZAR described dietary conditions in Switzerland. His country was surrounded by warring powers, and bread rationing had been necessary. Dr. DEMOLE dealt

research activities, and mentioned that a diet rich in vegetables containing vitamin C afforded some protection against whooping-cough.

International Problems

Dr. W. AYKROYD, of the United Nations Food and Agricultural Organization, explained that the nations exporting wheat had twenty million tons available, whereas the importing nations required thirty million tons. The present food crisis arose suddenly and demonstrated the need for a world food-intelligence service. Steps had now been taken to persuade nations to save wheat by increasing the extraction rate of flour, and by discouraging the feeding of wheat to animals. The International Emergency Food Council would act on the assumption that the basic daily requirement for western nations was 1,900 calories, and for eastern nations 20% less.

The two final sessions, at which Mr. A. L. BACHARACH and Dr. S. K. KOV presided, dealt with animal nutrition. In achieving its expressed aim of establishing contacts between British and European nutritionists the conference was completely successful. Few can have left without a broader outlook on the international aspects of nutrition, and a keener appreciation of the problems to be faced.

Correspondence

Work for the Disabled

SIR,—The language in which official pronouncements are couched has a peculiarly numbing effect on the average mind, and when it was noted in the House of Commons on July 30 that the Minister of Labour had made an Order under the Disabled Persons (Employment) Act, 1944, that the standard quota will hereafter be raised from 2% to 3%, few medical men realized that they were witnessing an important stage in the evolution of one of the great social reforms in the history of this country.

Expressed in simple terms the Order means that employers must now include three disabled persons in every hundred of their employees: their former obligation to the disabled was the employment of 2%; they must now employ not less than 3%. Has this any particular significance? Does it mean anything to the average practitioner of medicine? It does indeed. It is the complete answer to correspondents who in recent months have criticized the action of employers in persuading disabled employees to register under the Act even although they were already engaged in work. It is also the answer to the criticism of your leader (June 29, p. 990) that the "typical Civil Service approach to the problem . . . does not even achieve its object, since it merely means that the 2% will be made up of those with flat feet and subject to bronchitis." The purpose of the Act is to ensure employment for every disabled person—that is to say, for every person who has a handicap in seeking or keeping employment, no matter whether his handicap is simple flat foot or bronchitis, or grave deformity or disease. Every such person should register no matter whether he is already employed or not and no matter whether his handicap is serious or not. As the number on the register increases, so will the percentage obligation on the employer increase. Six months ago, when the Act was first introduced, the proportion was fixed at 2%. Since then 600,000 disabled persons have registered, including 50% surgical cases, 30% medical cases, and 5% psychiatric cases, many of them very seriously disabled. Of this number 50,000 are still unemployed. The increase in the quota from 2% to 3% offers employment for another 150,000 disabled persons, which should cover the immediate problem. But this increase is not only an assurance to those already registered who are unemployed; it is also an assurance to those who will register in the future. The quota will be increased still further as soon as increase is justified by numbers. The scheme may perhaps bear the stamp of the Civil Service mind, but, whether that is a good thing or a bad thing, it bears the stamp of an organized plan by which to guarantee employment for every disabled person.

In the leading article to which reference is made emphasis was also placed on the importance of securing employment

"for those grossly incapacitated." This presumably refers to patients whose incapacity is so serious that they cannot in any circumstances compete with the able-bodied on an economic basis. It must first be emphasized that few fall into this category. In the case of the vast majority of disabled patients the problem is only to secure the right type of employment; if this is secured the possibility of successful competition with the able-bodied has been proved time and again. Placement is, of course, difficult. It calls for co-operation between medicine and industry; it demands the skilled service of well-trained Disablement Rehabilitation Officers, suitably aided by medical boards in hospitals and directed by regional medical consultants, working in harmony with industrial medical officers; it demands all the research into industrial health which can be achieved; it requires the co-operation of every medical man. All this is recognized by the Ministry of Labour and the medical committee of its National Advisory Council, and active steps have already been taken to ensure suitable training and medical direction of Disablement Rehabilitation Officers. But it must be acknowledged that some patients remain for whom sheltered employment is the only possible answer. This is the task of the Disabled Persons Employment Corporation. Three factories have already been established by this Corporation; they are in active production and others will be established in the near future. Almost insurmountable difficulties have arisen, but nevertheless energetic steps are being taken to secure employment, not only for those who are incapable of competing with the normal output of able-bodied men, but also for those who are incapable of engaging in normal hours of labour.

No one who applies his mind to these tasks believes that they are easy of solution, and no one imagines that the solution is to be found without the commission of error; but recent experience in the course of a series of lectures in Canada and the United States reaffirms my belief that simple recognition of the problem, and the resolute attempt to solve it, has in itself brought credit to this country.—I am, etc.,

REGINALD WATSON-JONES,
Chairman Medical Committee, National Advisory
Council on the Employment of the Disabled.

Demobilized Specialists

SIR,—I have read with interest the letter from the Presidents of the Royal Colleges (July 27, p. 134). There is no doubt that the situation to which they draw attention really does exist and is causing very great anxiety to the demobilized specialists concerned. The suggestions they put forward are constructive and if accepted would prove a great boon to many. Unfortunately, they are already too late.

A large number of men who qualified in the months and years immediately before the war joined up in late 1939 and early 1940, and after varying periods of service and experience were accepted as trainees and eventually passed on to specialist work. These men usually had not had the opportunity of taking higher qualifications, but, after instruction and observation by senior consultants, were considered to have the professional and other qualities necessary to the Service specialist. A large proportion of these men were demobilized at the end of 1945 and beginning of 1946, and have now completed, or are about to complete, the six months' hospital appointments offered to them.

What of their future? Some have obtained the higher diplomas they lacked; some have not; but in either case they are faced with the problem of supporting themselves (and many of them have families) in the almost complete absence of any prospect of employment.

The Presidents of the Colleges have said: "... a reservoir of most useful recruits for the consultant service of the future will be lost." That is true, but I fear the final phrase should read: "... has been lost," for many of these men have had to give up their ambitions of a consultant career and have turned to general practice. This, when the bitterness has passed, will be greatly to the advantage of general practice, but with the introduction of any National Health Service the greater shortage will be of specialists and these men will no longer be available.

Here I think I may be permitted a personal note as illustration. I joined the R.A.M.C. in 1939 and, apart from the first six months, spent the whole of six years' service in military

hospitals (through no special manœuvring of my own!). After some four years I was classified as a graded physician, and eighteen months later was advanced to specialist physician with the rank of major. During the last two years of my service I was accustomed to considerable responsibility and to directing the work of junior medical officers. After demobilization I, in common with many similarly placed colleagues, applied for and obtained an appointment at my own London teaching hospital, with the object of consolidating my experience and of working for the M.R.C.P. Unfortunately, under the system in operation at this hospital, demobilized doctors are divided into two groups—those with, and those without, higher qualifications, and are paid salaries, respectively, of £550 plus £100 and £350 plus £100 regardless of their Service experience.

The example of one colleague who served in the same overseas command as myself serves to illustrate the inequity of this arrangement. He had been classified as a specialist physician for several years and after a very varied experience was, during his last six months in the Army, appointed officer i/c division. Since returning to his hospital to work for his diploma he has been employed as a junior house-officer with an income of £350 plus £100!

My appointment is now about to end, and as I found that I could not support my family on this income, and there was no prospect of any further employment at the end of six months, instead of devoting my time to preparing for an examination I have been travelling about the country interviewing agencies and doctors in an effort to find a suitable practice in congenial surroundings. I have been fortunate, and have at last succeeded in my quest, but many of my contemporaries are still searching.

If my case were an isolated one it would be of no interest, but I wish to stress the fact that there are many men similarly placed who are anxious, and well equipped, to continue in consultant work but who cannot hold on much longer without the prospect of reasonable employment at a sufficient income. Many, perforce, have made their choice, but others are still struggling along, and if some such scheme as the Presidents of the Royal Colleges suggest could be put into practice it would help to stop this wastage of potential consultants, but it must be done quickly. The matter is urgent.

In order not to cause embarrassment to my future partners in practice I shall use a pseudonym, but if any of your readers really wish to know my identity I trust, Sir, that you will not withhold it.—I am, etc.,

London, N.W.

SPECIALIST (late).

SIR,—As one of "the 800," I should like to express satisfaction and thanks for the letter from the Presidents of the three Royal Colleges (July 27, p. 134). Should their suggestion be adopted, however, I feel that the present scale of remuneration is inadequate for so long a period, and would suggest that, subject to satisfactory service, an increase in pay of £200 per annum after the first twelve months is an absolute necessity.

Many of us are over 35 years of age, with families to bring up and educate in the meantime, and with the present rising cost of living more and more dips into capital are having to be made. Unless some such provision is made, many good men of "the 800" will have to go into general practice long before April, 1948.—I am, etc.,

Epping

GORDON S. A. KNOWLES.

SIR,—I feel sure that the Presidents of the three Royal Colleges will receive the whole-hearted support of the profession in their endeavour (July 27, p. 134) to obtain assistance from the Government for the demobilized specialist who has either finished his educational rehabilitation or, as a recognized specialist, has returned to practice. Those who were well established before the war may have been able to re-establish themselves; but the young man who was called up just as he was about to acquire a suitable hospital appointment, or was in the early days of such an appointment, is having an extremely hard time.

If it were possible for the Local Medical War Committee or a similar organization to invite him to replace a specialist whose

call-up is now due, or to fill hospital vacancies, prior to election of a permanent member to their staff, on a sessional basis similar to that prevailing in the Emergency Medical Service, it would be helpful to all concerned.—I am, etc.,

Liverpool, 1.

R. KENNON.

Health Service Bill

SIR,—Surely every doctor has by now read the momentous information in the *Journal*, Aug. 3, and surely every doctor will join with myself in offering our most sincere congratulations and thanks to Dr. H. Guy Dain for his address as Chairman of Council at the Annual Representative Meeting. Several correspondents have written from time to time asking that the B.M.A. should give the profession a lead in its attitude to the National Health Service Bill, and I would submit that Dr. Guy Dain has now given all of us the lead for which we have been waiting. It is difficult for any single doctor to make up his mind definitely, by himself, as to the course he will pursue should the present Bill become law (as it probably will), but our course has now been set for us, and if the profession will now cast aside all doubts, all hesitation, all "sitting on the fence," and rally solidly behind the Chairman of Council we shall manage to save ourselves from bureaucracy and a medical dictatorship. I would go further and say that any medical man who still hesitates will deserve all that the State medical service will inflict upon him and more, for he will be betraying his colleagues.

The question of flouting a law does not arise, as even the Minister of Health has said a doctor does not need to join the Service unless he likes; consequently 50,000 doctors do not need to join the Service either. Let every doctor then stand firm for freedom, and support Dr. Dain and the B.M.A. to the limit before the medical profession becomes extinct. Let us remember that this matter does not concern England and Wales only, but all doctors in the British Isles must rally to support one another. We must all realize, as Dr. E. A. Gregg pointed out, that it will mean "blood and tears and toil and sweat," but surely even this will be better than selling ourselves and our profession for ever. Some doctors are at present going abroad, others are trying to decide between going abroad or giving up their profession rather than become political pawns, and these are grave decisions to make—even blood and tears and toil and sweat are preferable to preserve our ideals. Arising from this, would it be possible in some way to pool the profits of practices so that those who are badly hit in their adherence to the cause may be compensated by sharing in the profits of others who are better off? Personally I have signed to contribute to the Fighting Fund (and, only to show my sincerity, for more than the £25 suggested), and I for one will be very pleased to contribute, along with others, a proportion to a fund to reimburse those who have less remunerative practices or who are likely to be in straitened circumstances. This would be an annual payment out of profits, and would last until the present crisis is past.

One thing is certain: the even tenor of our professional lives will be inevitably disturbed, and we must choose between a dishonourable capitulation to the State or to make sacrifices ourselves, even to the extent of pooling our incomes so that we may remain free and keep others free. Let every doctor rally behind Dr. Guy Dain, supposing we have to scrub our own surgeries.—I am, etc.,

Kirkcubright.

J. McINTOSH RATTRAY.

SIR,—Many of us will have read with a sense of bitter disappointment the account of the discussion of the National Health Service Bill at the Annual Representative Meeting last week, and the decision to submit to a referendum of the whole profession the question as to whether negotiations on Regulations should take place. We are faced by constructive proposals by the Minister for the new service and apparently nothing but destructive criticism by our own leaders. The result of a referendum on such terms must be a foregone conclusion, and it can do nothing but weaken our position. It is obvious that a Bill of this nature is bound to come into operation. It should also be obvious that however much we may wish to retain the right to buy and sell our practices, it is

coming economically impossible to continue this system. How can the average young doctor find, say, £7,000 capital to pay for his practice, house, furniture, and car? And how can he ever pay off a loan from his bank under present rates of taxation? Times are changing and we must adapt ourselves to them.

Most of us will feel, after reading Dr. Dain's speech, that ministerial autocracy is the greatest danger to a satisfactory service, and that the Bill in its present form gives the Minister most absolute control of the profession. We are all anxious to co-operate in an effort to improve the medical services of the country so that they may become a model of efficiency. We have agreed that "many points in the Bill are excellent." Is it too late to demand that this issue, which affects every man, woman, and child in the country, be lifted out of the atmosphere of party politics? Can we not say that we would be willing to be anxious to co-operate in it if a committee of the best brains in the country, free from any partisan bias, were appointed to consider how this Bill could be modified to produce such a service?

If this is now impossible, cannot we be given some clear indication of what our positive policy is, and be clearly told what amendments to the Bill are considered so vital that we should refuse to operate, it unless they are introduced?—I am, etc.,

Goring.

L. G. BOURDILLON.

SIR,—The word "Quisling," appearing twice in your report *Supplement*, Aug. 3) of the Annual Representative Meeting, makes pathetic reading. It would now seem that those of us who have looked forward since our student days to a comprehensive health service for the nation, and who mean to take part in it given the honour so to do, are to be classified as traitors. Traitors to what? The cause of medicine and the well-being of the people? Or traitors to the interests of Mr. Lawrence Abel and others like him? Do Drs. Burnell and Robinson really think that we would be deterred by an appearance before the B.M.A. Ethical Committee? I for one would welcome the opportunity. It would give me a chance at long last to tell them that they should have been busy ere this pursuing those dishonest doctors who failed to carry out their obligations to their comrades in the Services, and who, now being safely established, will not even give them a fair chance to start again; who are now loudest in their protestations against inevitable change, and who seem to think a legally binding document is a mere scrap of paper.

It would be wise not to attempt to interfere with those of us who mean to support what will soon be the law of the land. The B.M.A. has already lost a great deal of public sympathy by its attitude and its cheap propaganda. Let it not make the fatal and final error of persecuting what it imagines to be a minority. Surely there has been sufficient warning in recent years of the idiocy of such a policy.

The Minister of Health has said that without the co-operation of the profession the Health Service will fail. He has deplored that this should have been made a political issue. Yet Dr. Guy Dain in his address persists in this attitude. "Some of us are Socialists and some are not," he says. We are, however, all members of the B.M.A., and I for one do not want it to be made the laughing-stock of future generations of men who will be doctors because it is their vocation, and who will compete with each other not for money but for the honour of belonging to a health service which has as its only objective the physical, mental, and moral welfare of the people. And it is people, not professions, that matter.—I am, etc.,

Okehampton.

C. G. JONES.

SIR,—In my opinion many of the vital decisions made at the S.R.M. held in May do not represent the considered opinions of the majority of doctors in this country. My Division, Winchester, may be taken to represent a fair cross-section of the profession, urban and rural. At a meeting of this Division held in April, resolutions were passed approving (1) limited negative control; (2) State ownership of hospitals; (3) Government compensation for loss of practice. The voting at the S.R.M. on these points was as follows: (1) 214 to 2 against; (2) 210 to 29 against; (3) 229 to 12 against.

It is extremely odd that apart from Winchester only one Division in the whole country was in favour of the very necessary degree of limited negative control which, with 100% inclusion, is essential in the interests of doctors themselves. Something is wrong somewhere. Now we are faced with a referendum of the whole profession on the simple issue of whether negotiations on Regulations with the Minister shall take place or not. Blank refusal to negotiate is an unsound position and will alienate all sympathy from Parliament, public, and press. I think rightly so.

The Regulations will be framed by the Minister with or without co-operation from the doctors. The chance to assist in moulding these Regulations in accordance with the accepted principles of the profession will be gone for ever. A blow will be dealt to the profession from which it will never recover. It is essential that each doctor should give deep consideration to his own interests and those of his colleagues. The straight answer to the straight question, "Shall we negotiate?" is clearly "Yes." As the Chairman of Council points out, a negative reply is irrevocable. He who thus decides is pledged not to accept service under the Act. Many will be thereby ruined. I forecast that 75% of the profession will answer, "Yes." Any other decision is suicidal (while of unsound mind).—I am, etc.,

Bordon.

C. NEWTON-DAVIS.

Private Practice—A Principal Issue

SIR,—That private practice should continue in the presence of a National Health Service has been recognized repeatedly at meetings of the Representative Body and by the profession in general as being the only certain safeguard for the freedom of patients and doctors against a monopoly. It has been recognized also that it is not enough to maintain the right of private consultation but that all the facilities essential for modern methods of diagnosis and treatment, especially including independent nursing institutions, must be available for private patients. Yet the provisions of the Bill which has now passed through the Commons give the Minister power to acquire compulsorily private institutions, and in this and other ways to destroy private practice whenever he may see fit. From several statements it is clearly the intention of the Minister and of his political party to abolish or to squeeze out private practice as soon as convenient, and in truth the provisions of the Bill giving this power met with no determined opposition from the other parties. The threat to continuance of private practice has thus become a principal, if not indeed the principal, point which the profession must take into account in deciding whether or not to take part in the Service, and before that in the making of the Regulations under the Act.

It does not seem, however, that the Council of the Association fully realizes the importance of this point, although through resolutions of the R.B. the preservation of private practice is in the policy of the Association. The Chairman of Council made only a brief reference to it in his remarks at the recent A.R.M.; and the recommendations of the Council for continuance of private practice presuppose, at least as to institutional facilities, such practice operating through publicly managed hospitals. There can be no doubt, however, that there would be no certainty of private practice continuing in that way, and that without independent institutions such practice may not survive.

A decision not to take part in a vital service set up by Act of Parliament, thereby to prevent its operation, could be maintained only with the understanding and sympathy of the public. Such understanding is not likely to be awakened by arguments, however sound, about the inadequacy of the Service, the ownership and management of the public hospitals, or the failure to consult with the profession in the making of the Service. Only on the moral ground of freedom for patient and doctor could there be public understanding of refusal. The profession has no stronger moral ground for refusal than in the power of the Minister to abolish private practice, for without the alternative of independent private practice there will be no real freedom for patient or doctor.

It is to be hoped, therefore, that the Council will put the threat to private practice under the Bill among the foremost points at issue which it will place before the profession when the plebiscite is held.—I am, etc.,

Bournemouth.

N. ROSS SMITH.

Negotiators and Legal Advice

SIR,—I think that most doctors will agree that the members of the Negotiating Committee of the Insurance Acts Committee have been singularly unfortunate in their deliberations with the Ministry of Health. I appreciate and gratefully acknowledge the great amount of work and time that all the members of these committees have expended for the general good of the doctors, but after all they are doctors themselves and not professional negotiators. I know that the B.M.A. does obtain legal advice, but this is not enough. In my opinion, the B.M.A. should procure the best possible barrister obtainable to undertake all necessary future negotiations with the Ministry, because it will be necessary for deliberations to take place whatever the result of the proposed plebiscite—otherwise the doctors will become entirely subservient.

In an interview I had recently with a Labour M.P.—a man who has been a negotiator on behalf of his union for many years—this sentiment was endorsed.

It would be interesting if other doctors would express their views on this important matter.—I am, etc.,

GEOFFREY DUDLEY.

The Doctor's Dilemma

SIR,—Under the heading "Demobilized Specialists" (July 27, p. 134) the Presidents of the Royal Colleges of Surgeons, Physicians, and Obstetricians and Gynaecologists respectively have painted a gloomy picture showing that the spectre of unemployment is stalking among the ranks of demobilized specialists.

What is the position among G.P.s? I quote a statement from the current bulletin of the Socialist Medical Association: "Applicants for assistantships were out of proportion to the number of vacancies available." What can this mean but unemployment?

I am quite aware that in 1948, when the Health Bill starts to operate, we shall be short of doctors, dentists, and most probably many other things as well. What interests the demobilized doctor is not so much what may happen in 1948, but what is going to happen in the few remaining months of 1946.—I am, etc.,

Southernport, Lancs

JOHN H. HANNAN.

The Plebiscite

SIR,—Before the plebiscite goes out to us all it behoves us very seriously to consider, and very clearly to see, what the issue really is. Quite obviously it is *not* a matter of finance: to many a salary is more comfortable than a winter rush and a summer stagnation. Nor is it an issue where selfishness enters. It is an altruistic choice we must make on the sole grounds of honour and humanity.

For nearly four thousand years the Christ-like spirit of our Hippocratic Magna Carta has stood for all that is decent and honourable in our profession. The spirit of that oath has produced a profession which daily performs more for humanity—without thought of personal gain—than all others put together. The ultimate analysis that is the birthright we are asked by the would-be dictator to sell for a mess of Marxian pottage. We are to desecrate the wishes of the dead upheld by British justice through the centuries. We are to prostitute uncoerced charity and voluntary free will to a bureaucratic autarchy. How dangerous this is! The annals of medicine clearly show that every advance in the healing art and appurtenances thereof came through voluntary and sacrificial effort.

Think of the great ones of our profession who cheerfully laid down their lives to alleviate this or that scourge of humanity. Remember the yellow fever investigators and all those other heroes. Can you see the Bevan Boys rising to any comparable altruistic heights under the scourge of Whitehall with its avalanche of forms and impersonal directorates? I throw out.

If enough of us are conscious of the priceless value of our honour this disgrace will not fall upon us, nor can we ultimately lose our free heritage. I am certain that we will have the vision to see, the heart to understand, and the power to prevail.—I am, etc.,

Loughton.

G. B. KIRKLAND.

SIR,—I am sure every doctor who has read the full statement made by Dr. Guy Dain (Aug. 3, p. 168), will have a thrill of pride at the first clear-cut, emphatic, and straightforward letter we have received from the B.M.A. as to our position in the impending National Health Service Bill. Either we want it or we don't; and let us have an immediate "Yes" or "No" from the profession by sending out a questionnaire something like the following lines:

Are you in favour of negotiations taking place on the matter of Regulations and the drawing up of the scheme? Yes or No. If "No," it will be assumed that you reject the scheme absolutely, whatever form it may take.

Dr. Dain says truly that "there are no other doctors but the doctors who are qualified. We are in the strongest possible position for ensuring that what we think is best for the public will be carried out."

Finally, a word to the returned Service doctors who themselves have found the change-over none too easy. No one would object to my mixing medicine with religion and literature, the latter two contain much good advice applicable to the present day. We require faith, which is excellently defined in Hebrews xi, 1: "Faith is the substance of things hoped for, the evidence of things not seen." While Shakespeare says:

"Our doubts are traitors,
And make us lose the good we oft might win
By failing to attempt."

Let us remember the motto which carried the Imperial Province safely through its hour of trial some thirty years ago and, substituting the first and fifth words, take as our watchword, "Doctors will fight, and Doctors will be right." I am, etc.,

Appleby Magna.

J. R. SALMOND.

Tuberculosis under the Bill

SIR,—I think that the majority of experienced tuberculosis physicians will agree with the general remarks expressed in your annotation (July 6, p. 20), and Dr. Hugh Ramsay's letter (July 27, p. 135). The importance of co-ordination of all measures affecting the tuberculosis patient cannot be over-estimated. It was one of the basic principles formulated by Sir Robert Philip well over fifty years ago on founding the first tuberculosis dispensary. It was endorsed by the Astor Committee in 1911 and since then up to the present day has stood the test of time. To quote Philip (*Journal*, 1906, 2, 1529):

"The tuberculosis dispensary should be, for every city or district, the uniting point of all other agencies. It should not be an isolated institution, but form an integral part, indeed the centre, of a general network of operations. . . . It cannot be too strongly emphasized that the strength of such a scheme lies especially in its organization and co-ordination. Each factor is doubtless of value. Each department has its own sphere of operations. As isolated elements the possibilities are relatively limited. In proportion as the various departments are intimately connected and co-ordinated, they can become more serviceable. The key to complete success in the campaign against consumption lies in the harmonious co-ordination of well-directed measures." (My italics.)

These remarks apply with even greater force to-day in view of the ever-widening sphere of anti-tuberculosis activities especially in relation to mass fluorography and rehabilitation. If a tuberculosis scheme, therefore, is to function at the highest level of efficiency there must be unity of control, and seems rational that this should be vested in the tuberculosis physician, who has a sound knowledge of the patients' requirements. In addition to the tuberculosis physician's examination and assessment it is desirable that the patient should undergo a psychological examination, chiefly for rehabilitation purposes: so that his mental aptitude or otherwise for certain well-defined types of work may be made manifest. For this reason a specialist psychologist should be attached to the consulting staff of the tuberculosis scheme. In this connexion preliminary observations of the 1944 Disablement Act suggest that more detailed attention to the patient's mental make-up is necessary if the placing of "square pegs in round holes" is to be avoided.

The proposal to link the tuberculosis dispensary to the general hospital should meet with wide approval, but it is essential that the individuality of the dispensary be maintained. As one who has been for many years on the visiting staff of a county general hospital, which for a period housed a che-

surgical unit, the writer can speak from experience of the advantages gained from such close association. Apart from the activities of the out-patient department of a general hospital the in-patient department should have two main functions in respect of tuberculosis. First, in-patient investigation of chest cases seen at dispensaries or elsewhere which require further investigation to establish the differential diagnosis. Secondly, cases of definite tuberculosis, mainly minimal lesions, whose condition is doubtfully active and requires accurate assessment. Cases in either of these categories found to require treatment should be transferred to the appropriate institution for pulmonary tuberculosis, but non-tuberculous cases would be retained in the hospital. Valuable beds in sanatoria required for the urgent treatment of active progressive lesions are thus unblocked and the long waiting-list materially reduced. The tuberculosis physician's main duties at the general hospital therefore should be to "pin-point" the diagnosis, and where the patient is found to be tuberculous to assess the state of activity and determine manner of disposal. It is obvious that with the development of mass fluorography, as yet in its extreme infancy, many more beds will be required for these investigations.

At the present time there are over one hundred and eighty committees throughout the country concerned with the administration of tuberculosis schemes. *Quot homines, tot sententiae!* Can it be wondered, then, that there is such a divergence in the standard of efficiency attained in the operation of these schemes? The following story may not be irrelevant. An Englishman touring the Scottish Highlands called at a wayside inn, and was surprised at being able to obtain alcoholic refreshment outside the usual licensing hours. "Is there any difference in the law here?" he inquired. "Nae deference in the law, but a great deference in the interpretation thereof!" was the reply.

The new Bill offers an excellent opportunity for reviewing the present scheme throughout the country and eradicating existing defects. Let us then build up a first-class, integrated, national scheme which will keep Britain in the forefront of the campaign against tuberculosis, and so fulfil even the most sanguine hopes of the early pioneers, both those whose names are recorded, and also those who have gone "unhonoured and unsung."—I am, etc.,

Chester.

D. W. TOUGH.

Congenital Malaria

SIR,—During part of June and July this year I had blood-films from 31 mothers and their newly born babies examined (June 22, p. 966). In every case the mother's blood was taken from the finger, and the baby's from the umbilical cord at birth. Out of the 31 cases 14 mothers and 5 of their babies had malarial parasites, malignant tertian; and 6 mothers and 3 of their babies had benign tertian parasites.—I am, etc.,

Cawnpore.

C. B. ADDERLEY.

Transurethral Prostatectomy

SIR,—After the numerous papers and letters recently contributed to various journals by the advocates of abdominal prostatectomy and the originators of new technical methods, I much appreciated the refreshing note of stability struck by Mr. W. E. M. Wardill's letter (July 20, p. 100), and I entirely agree with his observations on transurethral prostatectomy.

Hey and Millin have not only written about their respective techniques of abdominal prostatectomy, but have criticized the transurethral route. Most criticisms of transurethral prostatectomy—to which the above are no exceptions—are, I believe, misleading or inaccurate. Hey's observations bear no relation whatever to transurethral prostatectomy except that of simple inaccuracy. Transurethral prostatectomy, especially in comparison with abdominal prostatectomy, must be judged according to its mortality rate, morbidity rate, and operability rate for comparable cases. It is according to these standards that the operation will stand or fall. The advantage in operability and mortality rates for comparable cases lies overwhelmingly with the transurethral route. Since the adoption of this route the whole scope of prostatic surgery has been vastly increased to include the large group of very aged prostates quite unfit for abdominal prostatectomy, and to render safe for surgery the

much larger border-line group of bad risks. The whole group of permanent ambulatory suprapubic cystostomies—a large one in municipal hospitals—has, in my personal experience, now disappeared. The results of transurethral prostatectomy using the Thompson cold punch after adequate experience (over one hundred cases) have on the whole been much better than the results following suprapubic prostatectomy.

In January of this year Millin gave his total for transurethral resection as 219 and (*Proc. roy. Soc. Med.*, 1946, 39, 328) went on to say, "I can claim, I think, a wider experience of these operations (loop and punch transurethral resections) than anyone in this country." One does recall, however, that Wardill's published total was 230 cases five years ago. My own total is 369 cases—97 treated by the diathermy loop and 272 by the Thompson cold punch.—I am, etc.,

Manchester.

H. T. COX.

The Catheter and the Prostate

SIR,—Mr. W. E. M. Wardill (July 20, p. 100) presents a strong case for prostatectomy with the cold punch; but in his letter he fails to make clear the great difficulties associated with this operation, though admittedly he has done so elsewhere (*Lancet*, 1941, 2, 127). I agree with him that the operation can be very satisfactory and gives a low mortality when expertly performed; but it requires a very high degree of technical skill to remove an adequate amount of gland; and a large experience, probably some five hundred cases, is necessary before this proficiency can be attained. A further difficulty is the need for intensive after-care, which requires a team of trained assistants and orderlies, preferably housed in a special department, such as the one at Newcastle.

In a small experience of some one hundred consecutive cases operated on with the Thompson punch I was able to raise my operation rate for prostate patients to 90% with a mortality of just over 9%, but the strain on the theatre and ward staffs in a crowded general hospital was very great. Furthermore, a number of these cases had sooner or later to be done again on account of incomplete removal of prostatic tissue. Also, haemorrhage is sometimes very difficult to control; and that urethral complications are not infrequent is shown by the increasing use of a perineal urethrotomy in some American clinics.

I therefore turned to the Hey operation, and up to the end of January this year had operated on 62 cases out of 65 admissions (two admitted moribund, and one refused operation). There were altogether six deaths: uraemia—2 cases, 8th and 9th day, aged 78 and 67; pneumonia—2 cases, 4th and 53rd day, aged 83 and 73; senility and cardiac failure—1 case, 10th day, aged 88; streptococcal septicaemia—1 case, 21st day, aged 61 (cross-infection in ward). Thirty-three cases came in with acute retention, with one fatality in this group. As with Mr. Wardill, no case is refused operation if there is the faintest chance of recovery, the average age of the fatal cases being 75 years.

Nearly all your correspondents have criticized Mr. Wilson Hey's methods adversely, but from reading their letters it would appear that none of them has given "aseptic prostatectomy" a fair trial. The Hey procedure has definite advantages: it ensures complete removal of the gland, requires a minimum of pre- and post-operative treatment, and the cases can therefore be nursed in the surgical wards of a general hospital. Also, the stay in hospital is comparatively brief—an important point with the present shortage of hospital beds. Lastly, a very high proportion of prostate cases can be offered the chance of permanent relief with a reasonable over-all mortality rate. Lately, I have combined Mr. Wilson Hey's principles with the Millin retro-pubic approach, which presents some attractive features—notably, good haemostasis and absence of a bladder wound; but it is as yet too early to assess the value of this combination.—I am, etc.,

Lincoln.

G. A. BAGOT WALTERS.

SIR,—Mr. W. E. M. Wardill, in his forceful letter (July 20, p. 100), writes from want of knowledge of my operation, the type of patient, and the standard of operability. He has yet to see a prostate removed aseptically, and the results. He is quite unaware of the extraordinary care taken in diagnosis both before and during the operation. It is well realized that urinary

retention in the presence of an enlarged prostate may be due to some other cause, perhaps in the abdomen, which can be and often is explored during my operation without shock, and at the slightest provocation. Prostatic obstruction can no longer be considered as an entity in-itself as the cause of obstruction. Prostatectomy has entered upon a new era.

Mr. Wardill believes that the septic transurethral route should be the only one. I hold that whilst the transurethral method has a definite place (*Brit. J. Surg.*, July, 1945) the transvesical route, with full investigation of the bladder, and, if necessary, abdomen, is generally the wiser route. There must be at least six ways of dealing with any individual prostatic obstruction. Mr. Aneurin Bevan could create for himself everlasting fame in surgical history if he would appoint investigators with full powers to evaluate the results and tell the world which method is the best. This would apply in cancer of the breast and many other diseases. Each surgeon now ploughs a lonely surgical furrow, believing that his method is the best, in spite of the journals, his clubs, societies, and conferences. Assessment and evaluation of results should be in the hands of experienced judges. Mr. Wardill's chief objections are to my refusal to pass the cystoscope to diagnose the disease, and the catheter to relieve the patient. If the cause of the urinary retention is in any doubt, of course the catheter or cystoscope must be passed; but the infection occasioned thereby must be allowed to recover before an operation is permissible. It is quite true that many a catheter has been passed only once and never required again. But it is chronic, not acute, retention that kills, and the prostate is allowed to grow and ultimately by some complication assist in the patient's death. We are all asking the prostate patient to come early, but Mr. Wardill refuses his first urgent and most definite indication. He suggests that his cases are worse than mine. Well, I have refused no case of any type this year, and during this week three patients died before they could be admitted to nursing homes and each one of them had been waiting less than a week. Such is the standard of aseptic prostatectomy, and I doubt if such a standard has ever been set in any other type of prostatectomy, including transurethral resection. My figures include cases as bad as these.

"Simple suprapubic cystotomy" is a far, far more dangerous procedure than aseptic prostatectomy, and any surgeon who declines "routine preparatory anti-infective therapy" is wantonly refusing to take advantage of the marvellous advances of science. At every operation of moment pre-operative anti-infective therapy should be the general rule, because with all the will in the world infection may come from the surgeon, his assistants, and even the patient himself. After all, the microbe is the greatest living enemy of mankind.—I am, etc.,

Manchester

WILSON H. HEY.

Intravenous Adrenaline in Asthma

SIR,—In status asthmaticus, Sir Arthur Hurst's method of continuously injecting adrenaline subcutaneously at the rate of 0.06 ml. every 15, 30 or 60 seconds (according to the patient's tolerance) usually brings relief, and it is generally agreed that this is the most satisfactory method of treatment. In a few cases, however, the condition shows a marked tendency to recur. A patient will be relieved of his asthma in the evening only to wake up in the morning with bronchial spasm just as bad as ever. When this happens, adrenaline has to be injected as often as is necessary to keep the patient free from asthma. Very often the succession of paroxysms soon comes to an end; further administration of adrenaline is not required, and one can then proceed to the general treatment and investigation of the patient. Occasionally, however, status asthmaticus persists, and a time comes when large amounts of adrenaline by the subcutaneous route have little effect. One can inject syringe-ful after syringe-ful without relieving the bronchial spasm to any appreciable extent, and without producing symptoms such as tremor or tachycardia.

When this stage has been reached, I have found adrenaline by the intravenous route remarkably successful. Severe bronchial spasm is completely abolished in about five minutes, when previously the continuous subcutaneous injection of adrenaline for the best part of an hour has had little effect. I should emphasize that I have given adrenaline intravenously only when

the injection of 1 ml. subcutaneously straight off has ceased to produce subjective symptoms such as tremor. The technique is as follows:

A tuberculin syringe graduated in hundredths of a ml. is used, and 0.15 ml. of a solution of adrenaline (1 in 1,000) is drawn into it. This is diluted to 1 ml. with sterile water, and of this 0.05 ml. is injected very slowly intravenously, and a pause made. At this point the patient experiences what he describes as a feeling of suffocation, and the bronchial spasm appears to become more severe. I have never seen tremor, tachycardia, or palpitations produced. This reaction passes off in a few seconds, after which the contents of the syringe are injected at the rate of 0.1 ml. every 30 seconds. No further subjective discomfort is experienced, and the bronchial spasm disappears. I usually follow up the intravenous injection by a subcutaneous injection of adrenaline to prolong its effect.

Aminophylline has been employed by some in "adrenaline-resistant" asthma, as has morphine, but these drugs are not always effective. In treating status asthmaticus I think a very important principle is to relieve bronchial spasm as completely as possible and as often as necessary. If this is done, the illness will be less prolonged, and less permanent damage will be done to the lungs.—I am, etc.,

Troon.

JAMES ROSS.

Migrainous Headaches

SIR,—Mr. Cecil Tivy (July 27, p. 138) appears determined to label Gasserian injection as necessarily causing total anaesthesia of the cornea. This is not so, as he might have learnt from Case 3 in my article of May 18 (p. 754), of a schoolboy in whom I injected only 3 minims (0.18 ml.) alcohol, producing light analgesia of V.1 and only diminished corneal reflex, but yet cure of his recurrent headaches.

Complete corneal anaesthesia following Gasserian injection is not such a serious handicap as Mr. Tivy seems to imagine, for if the eye is taken care of for a few weeks in the way I described in my letter of July 6 (p. 24), it usually gives no further trouble, as has been my experience in literally hundreds of cases. Severe keratitis and loss of sight in one eye is, of course, a serious occurrence, but it cannot compare with the crippling recurrent headaches of almost daily migraine, or the violent neuralgic spasms of trigeminal tic, which have often in the past led to suicide. Case 8, described in my article, indeed made such an attempt, but was subsequently cured by Gasserian injection, and though totally anaesthetic his eye has given no trouble. If my critic is still dissatisfied, I shall not trespass further on your valuable space.—I am, etc.,

London, W.1.

WILFRED HARRIS.

Paralytic Ileus

SIR,—In connexion with paralytic ileus, first described, as I believe, by Mr. Sampson Handley, and on which you have given us several communications lately, I should like to submit a surgical measure designed to forestall its happening. I have neither heard nor read of it in the literature, nor written of it hitherto. It is intended for all cases of appendicitis in which there is reason to fear that the pelvis is in danger of becoming involved, or suspected of being so already.

The old routine practice of first exploring and dealing with the region of the appendix and then proceeding through this inferno to explore and drain the pelvis is a piece of work which, surely, no surgeon can feel happy about. If upon doing this the pelvis be found already involved, no harm, of course, has been done. On the other hand, if not, and there be found but a pool of clean-looking serum, or none at all, then the surgeon's finger has spread the conflagration. I suggest that in fact such artificial extension is even worse for the patient than a gradual one due to progressive spread of the inflammatory process. General shock is increased and local too, well calculated, as if by scalding, to paralyse the coils of intestine lying there by suddenly drenching them in poisonous pus.

My plan is to anticipate this danger by traversing a clean route. The pelvis is explored through a small suprapubic incision by passing a small swab down over the bladder with a long pair of pressure-forceps. It will show what kind of effusion, if any, lies below. If unquestionably foul, we have at any rate probably done no harm. But if not obviously foul, a tube no larger than a pencil is passed right down to the bottom, its outward end turned 3 or 4 inches (7.5 or 10 cm.) away to the left, and wrapped in anti-septic gauze and wool. This done, the wound is stitched up round the tube and

thoroughly covered with antiseptic dressings. Now, and only now, may the main focus be approached, and the further to the right the incision is placed the safer for the plan. Final drainage through a stab-wound in the flank will still further diminish the danger of contamination of the suprapubic wound. It seems difficult to me to overestimate the value of the pelvic tube as a safeguard, for it cannot be denied that even the gentlest handling may be too much for the barrier of peritoneal adhesion bounding the primary abscess, and even without this the process may spread by reason of its own virulence.

I have had no more than two or three opportunities of doing this since first thinking of the plan, but the effect was in every case thoroughly gratifying. The pelvic drain had done its work in a few days, normal peristalsis was quickly restored, and there was no contamination of the pelvic track. The original focus remained strictly localized.—I am, etc.,

Doncaster.

WALTER REGINALD WILSON.

Immunization with B.C.G.

SIR,—Referring to your leading article (July 27, p. 125) on the B.C.G. deputation to the Minister of Health, I may say that there has come to my notice, since the completion of the memorandum which was presented, a development of possible importance which you may care to make available as an addendum to the information contained in the memorandum. As usually prepared, B.C.G. vaccine must be used within a few days, and, faced with the problem of sending it to far distant places, Russian scientists have been experimenting with methods of preserving it in the dry state for longer periods. They have found (Leshchinskaya, E. N.: *The Immunizing Value of the B.C.G. Dry Glucose Vaccine. Amer. Rev. Soviet Med.*, 1946, 3, 210) that freeze-drying of a bacillary suspension in 50% glucose solution yields a product which retains full viability and immunizing efficacy for at least eighteen months.

A major difficulty in production at present is that the vaccine must be used before tests for virulence, or for the presence of virulent contaminants, can be completed, which necessitates the most rigid supervision and complicated precautions at all stages of preparation. If vaccine can be stored so that tests are complete before it is issued the process of production can be simplified both technically and administratively, and public confidence at the same time increased. Further, preparation of large batches at long intervals, rather than frequent small batches, may make for greater uniformity of dosage, and should reduce production costs. Preliminary experiments to test the efficacy of the Russian and of other comparable methods are at present under way.—I am, etc.,

Cardiff.

W. H. TYTLER.

The "Intractable" Vesico-vaginal Fistula

—SIR,—The object of my previous letter (May 18, p. 774) is achieved if I have been able to present a more hopeful picture of the curability of the vesico-vaginal fistula than that shown in certain recent publications—and reflected, it seemed, in Dr. Mackay's report—in which scores of uretero-colic transplantations have been recorded without, apparently, any adequate attempt having first been made in those cases to effect a direct repair of the bladder injury. With this main issue Drs. O. S. Heyns and P. Keen (July 20, p. 99) are more or less in agreement.

Dr. Heyns is, however, in error in supposing that I have the "impression that fistulae can be invariably cured by vaginal operation." I have never made so bold or unwarranted a statement. It is, however, my belief that the *great majority* of fistulae can be so cured, and in support I quoted a series of consecutive cases in which the opening had been closed by a straightforward plastic vaginal operation. It would be presumptuous of me to suppose—and I do not do so—that similar results can be obtained in the very different conditions that may obtain in other countries; nevertheless, the trend of my argument is unaltered, and is supported by Mahfouz's work in Egypt. There, also, cases are encountered which present problems of the greatest difficulty and complexity; there, also, many of the patients are debilitated by chronic disease; and there, also, the bladder is heavily infected with schistosomiasis. Yet Mahfouz was able to report after three hundred cases: "Of my last hundred cases I had 95% cured, 5% greatly improved."

(I apologize to Dr. Heyns for omitting the necessary second reference to this work; it is: *J. Obstet. Gynaec. Brit. Emp.*, 1930, 37, 566.) Excellent results have also been reported from India in a recent paper by Benion Thomas¹ of Madras.

I do not doubt that an unusually large proportion of the fistulae seen in native races such as the Bantu present features of special difficulty; but, although the patients seen in this country may conform to "a different clinical picture," Dr. Keen is wrong if he supposes that the cases quoted in my series were all of a simple nature. For example, more than half the patients had had previous operations—often multiple operations, six, eight, nine, and more—resulting in extensive and dense vaginal scarring. In several cases the fistula was adherent to the pubic ramus. In some the incontinence had lasted for many years—thirty-two in one case. In one the fistula was so large that the anterior wall of the bladder bulged into the vagina, and in another the bladder was completely everted and presented as a mass as large as a fist with the ureters spouting jets of urine from its surface. In several the cervix had sloughed off together with a variable amount of anterior vaginal wall; and in one the entire uterus had sloughed away (this patient² had been in labour for four days and had been delivered by the cranioclast). In one a radium burn had caused widespread destruction of bladder and rectum, resulting in the vagina's becoming a receptacle of both urine and faeces. In one the urethra had been torn from the bladder; and in two the urethra was entirely missing.²

It is with knowledge of these cases that I made the statement that the curability of vesico-vaginal fistulae is higher than is often supposed. Uretero-colonic transplantation—a formidable operation, although a godsend when alternative treatment is quite impossible—is but rarely required in fistula work; and this is also the opinion expressed by Mahfouz Pasha of Cairo. I am, etc.,

The Radcliffe Infirmary, Oxford.

Amenorrhoea during Internment

SIR,—Dr. Annie Sydenham's paper (Aug. 3, p. 159) on amenorrhoea during internment brings prominently before us the scantiness of our understanding of the aetiology of this type of amenorrhoea.

While it is generally recognized that change of environment, metabolic disturbances, and emotional shock may lead to amenorrhoea, the *modus operandi* of these causes is unknown. It is probable that the inhibiting factor operates at some point in the endocrine chain, but what this factor is, where it operates, and how it is brought into play are all matters of conjecture.

It may be of interest to record somewhat parallel observations made while I was attached to the hospital of a Yugoslav refugee camp in Egypt during the latter half of 1944. Unfortunately no statistics were compiled, so I can only record impressions. Even in these days when our lives are ordered by numbers it is to be hoped that impressions based on observations are pertinent. In any case, the existence of amenorrhoea in a large majority of the women in this camp cannot be doubted. The camp had a population of 30,000 refugees—women and children, and men of non-military age or fitness—who had arrived in Egypt in batches between Dec., 1943, and May, 1944. In taking menstrual histories from female patients the reply, with monotonous regularity, was of amenorrhoea since arriving in Egypt, or, and this particularly in girls in their teens, of one period only after arrival in Egypt and then no more. A Serbian doctor who had accompanied the first batch from Yugoslavia, and who acted as my interpreter, looked upon my routine inquiries for a menstrual history as a joke, for he had come to regard amenorrhoea as the normal condition. He attributed it to altered environment and climate. (With regard to climate, it would be interesting and instructive to know if any investigations were made on menstrual variations amongst British female auxiliaries serving in hot climates.)

As to aetiology: environmental and climatic change was operative in all cases. Emotional shock may be assumed to have been experienced by all. Gross malnutrition and severe physical hardship had been the lot of a proportion of this community before escaping from Yugoslavia. The distribution

of the sexes made for an abnormal social set-up. The majority of the married women in the age group under consideration were separated from their husbands; many were widows; more feared or presumed themselves to be widows. I had no opportunity for judging whether amenorrhoea was less prevalent among the minority who had their husbands with them, but among the pregnant it was noticeable that frequently the period of amenorrhoea exceeded the period of gestation.

One environmental condition having strong psychic influence struck me as a possible aetiological factor. The refugees were housed in large tents holding ten to twelve beds or mattresses packed close together on each side. Several families, including both sexes, would occupy one tent. During the early months, at least, washing facilities were very limited and ablutions took place in public. In discussing with camp officials (Yugoslav) the hardships they had endured, pride of place was given to lack of privacy; and as the outstanding example of this they instanced the difficulty experienced by women in washing sanitary towels—an operation performed stealthily by night. One wonders if outraged modesty had been an effective emotional cause in producing a welcome amenorrhoea.

Dr. Sydenham's statement, "Absence of menstruation was a convenience," very accurately describes the situation which existed in the Yugoslav camp.—I am, etc.;

Ipswich.

W. P. GRIEVE.

Rheumatic Fever

SIR,—Due probably to a poor choice of title, Dr. K. Douglas Wilkinson (Aug. 3, p. 174) seems to be under a misapprehension regarding the scope of my paper. I had hoped, however, that the subtitle would adequately indicate the nature of the contents. In fact the paper was a report upon the results of a convalescent centre, and the patients when admitted were convalescent. Many had been up-patients before transfer, and they came for a period of rest and a graduated return to activity. The first hospital to house the centre had been a country mansion taken over on the outbreak of war; the second hospital was a converted hydropathic establishment in the midlands. Neither offered laboratory facilities to make suitable investigations, even had they been worth while so late in the course of the disease. The nearest x-ray apparatus was some thirteen miles away, and needless to say x-ray examinations were made only in exceptional circumstances. Again, I think it most unlikely that any of the exciting appearances referred to by Dr. Wilkinson would have been seen at the stage of convalescence reached by these patients. Had it been possible for all rheumatic patients to be admitted under one roof from the outset of their illness such investigations as Dr. Wilkinson suggests would have been worth while. But they were scattered in small numbers throughout the country, and, quite apart from the problems of transportation, it is often and naturally difficult for a physician to relinquish a patient until pressure of bed space or a waning interest induces him to do so.

I am in entire agreement with Dr. Wilkinson that acute rheumatism is a very difficult subject, and my experience is sufficient for me to form an opinion on the question of allergy in the disease. Nor did I intend to convey the impression that I inclined to this belief, for as far as possible I have tried to keep an open mind on the subject. But when an authority like Coburn (1940) suggests that rheumatic fever is associated with abnormal immune response of the host due to heredity and environment, and discusses a state of sensitization of the reticulo-endothelial system in such an individual who does not handle respiratory infections with haemolytic streptococci in a normal manner, the opinion merits some consideration. This seems to me strangely like allergy, although it was perhaps rash of me to mention so controversial a subject. It may be better to regard the joint manifestations (which are not absolutely constant in rheumatic fever) as a non-specific reaction to the infection whether it be rheumatic, tuberculous, or due to a neurotropic virus. In invoking the effect of salicylates as his criterion for the specificity of the rheumatic joint manifestations it appears to me that Dr. Wilkinson is in danger of committing something akin to the logical fallacy of the undistributed middle. I suggest that the response of the joints is part of the general amelioration brought about by salicylates in much the same way that Sheldon (1946) found the joint

manifestations to subside with constitutional improvement tuberculosis.

Even the specificity of the Aschoff body seems no longer to be above suspicion. I realize that it is dangerous to draw from animal experiments, but it is interesting that Harr (1946), after the experimental pulmonary infection of rats with pneumococci and staphylococci, found typical Aschoff bodies scattered throughout the heart. Of greater importance are the findings of Baggenstoss and Rosenberg (1941) in twenty-five cases of rheumatoid arthritis at the Mayo Clinic. At necropsy rheumatic heart lesions were found in four cases and in seven of these there were typical Aschoff bodies. A history of rheumatic fever was obtained in only one of the cases.—I am, etc.,

Walton-on-Thames.

Deafness from Rubella in Pregnancy

SIR,—I have read with much interest the letter written by Dr. Muriel Barton Hall (May 11, p. 737) reporting a case of congenital cataract, heart disease, and deaf-mutism in association with an attack of rubella six weeks before conception of the child. In this connexion it may be mentioned that G (1941) described an instance of congenital cataract in a child whose mother had contracted German measles three months before pregnancy. Subsequently he (1944) recorded an example of deaf-mutism in which it was not improbable that the infection had preceded conception. My colleagues and I (1946) observed a doubtful case, and later (1946) two negative ones and postulated (1944) that the phenomenon could be explained on the basis of the known property of viruses of persisting in the tissues of the host for long periods of time after original infection. I hope therefore that other observers will be stimulated to record such cases, rather than to suppress them as Mr. Ivor Hughes (May 25, p. 813) would apparently like them to.—I am, etc.,

Adelaide, S.A.

Psychological Reactions in War-blinded

SIR,—Dr. W. M. Harrowes' most stimulating article "Psychological Reactions in the War-blinded" (July 27, p. 129) is of great interest to all ophthalmologists who had to deal with such casualties in the recent war. The following observations on cases which were treated in a Mobile Ophthalmic Unit of the Eighth Army between 1941 and 1943 may be considered relevant.

Early Reaction to Loss of Vision.—The stoicism of the grossly mutilated young men—Briton, Frenchman, Greek, Syrian alike—was amazing. Heavily bandaged from the moment by their rescuers they might spend from one to three days jolting helplessly over the appalling desert tracks. Quietly they let the dressings be removed, but inevitably demanded immediate prognosis as to the final function. This had to be given them in absolute truth, as any half-truth or evasion seemed quickly to be appreciated. But the extraneous noises of the now distant battle (and no doubt their knowledge of the protective value of canvas shelter and sandbags) put limits to their self-control. It was found impossible to expect full co-operation under local anaesthesia, and a "general" had to be used. Mr. H. B. Stallard found that by the time they reached the Hospital they were sufficiently restored to co-operate under local anaesthetic. In the canvas shelter the quiet of the wounded man appeared in strong contrast to the restless equally heavily bandaged "psychiatric blind." Possibly the really genuinely injured man had solace in the knowledge for him the seemingly endless sandy existence was finished. Two remarks stand out in my memory: one man saying before operation, "For God's sake watch yourselves, I've syphilis." The other later in Sicily, when in the remaining a fly maggot had crawled out from the anterior chamber

patient thanked me for "getting rid of those wrigglers"—his sole remark.

Late Reaction to Loss of Vision.—I often wondered about the adjustment and final mental state of such men, with their very different outlooks: the regular soldier, the volunteer, and the conscript. The man wounded in the line of duty must have some consolation denied to the poor fellow who, disregarding warnings, finally "bought" one of these fiendishly effective booby-traps. So early in 1945 I wrote around to get details of men who had been evacuated through our unit. Unfortunately only a few answers were received, but I would mention with considerable gratitude the very comprehensive "follow-ups" received from St. Dunstan's (Mr. R. C. Davenport) and the institute at Temboni, Wynberg, South Africa. Beyond details of purely ophthalmic interest I did note the number of men doing well at massage. Yet these men had spent three years or so digging a fresh slit-trench daily. All I could think of was a slender historical thread passing back through the ages to the blind priests of Aesculapius. I was duly dealt with when it was pointed out that after passing a very stiff selection board they were trained and were often amazingly successful.

Tension.—One thing I remarked was that several of the men who had been injured by booby-traps had been noted as difficult in adjustment. Lack of education provided another handicap, along with sensitivity as to appearance.

Over-compensation.—An ex-member of the Special Air Service, trained for aggressive tactics, provided an excellent example, similar to Case 40.

Re-stabilization.—The reports on the South Africans who had gone back to their farms, so continuing their pre-war tenor of life with minimal upset, were interesting.

To conclude, can we ask Dr. Harrowes for a further article on these forty cases in, say, another five years? Much further adjustment will be demanded from these men when they no longer make a vivid impression on the national conscience, but have been relegated to the position of yet another "Good Cause," to be propitiated by yet another flag-day.—I am, etc.,

Catterick Military Hospital.

G. C. DANSEY-BROWNING.

Sale of Tinned Meat

SIR,—Does not the recent outbreak at Witham of an epidemic of salmonella gastro-enteritis, which was found, as reported by Dr. F. E. Camps (July 27, p. 131), to have been started by the infection of slices of tinned meat in a butcher's shop, clearly show the danger of the present method of distribution of slices of tinned meat? I suggest that the medical advisers of the Ministry of Health look into this matter. Surely it would be safer to restrict the distribution to *grocers*, who would sell the sliced contents of opened tins at their bacon counter? Butchers should be allowed to sell whole unopened tins, but not meat from opened tins.—I am, etc.,

Leitchworth.

H. H. KING.

Book Reviewing

SIR,—In his letter on book reviewing, Mr. H. Osmond Clarke (July 20, p. 102) may not be so right as he thinks he is. But with regard to the case in point (*Injuries of the Knee-joint*), a perusal of the book indicates that your reviewer has done his work well. There are pros and cons in this subject. The system of anonymity, whereby reviews are entrusted to men who are selected because of their experience and special knowledge of the subject, has the advantage of allowing them to write impersonally and impartially without being exposed to the polemics of those who may not see eye to eye with them—e.g., the "pompous," "pontifical," and "unjustifiably censorious" adjectives which Mr. Clarke uses. The point that some reviewers may have already retired from practice is not in their disfavour: they bring to their subject a wide knowledge and experience in it, and they have sufficient leisure to make themselves *au fait* with all that is going on and can give your readers the benefit of a balanced retrospect.—I am, etc.,

Edinburgh.

G. DOUGLAS GRAY.

SIR,—As an author and also a book reviewer I heartily endorse Mr. H. Osmond Clarke's suggestion (July 20, p. 102) that the names of reviewers or their initials be appended to all reviews in the *Journal*. A well-known critic once said that a

reviewer's work can be done in three cuts: "First, cut it open, then cut it up, then cut it altogether." This laconic advice was meant to apply more especially to novel reviewing. In the case of medical works the procedure is not quite so simple. An unbiased critic—for nobody should attempt to review a book by an author against whom he may cherish some animosity, due, perhaps, to some ill-founded rumour or otherwise—should seize upon the good points *before* he pounces, hawk-like, upon the omissions. The latter may be relatively unimportant, or they may be out of the scope of the book as conceived by the author. The value of the first look-over as being likely to yield a correct impression upon the reviewer reminds us of Swift's dictum when he said, "Criticism, contrary to all other faculties of the intellect, is ever held the truest and best when it is the *very first result of the critic's mind*." (The italics are mine.) To concentrate unduly upon the faults and shortcomings of a book is, as Mr. Clarke remarks, most unhelpful, whereas friendly criticism and suggestions for improvement in the next edition will always help to gild the pill.

One reason for the preponderance of reviews of American works, pointed out by other correspondents, may be that publishers in the U.S.A. may not have been so hampered by paper restrictions as their British colleagues; but I do think that British works should definitely have the pride of place in the review columns of the *Journal*.—I am, etc.,

Ringwood.

G. NORMAN MEACHEN.

SIR,—“Who killed John Keats?” It is generally believed that, as often before and since, it was the tubercle bacillus. But the author of the opening phrase of doggerel thought that the writer of the lacerating, unsigned notice in the *Edinburgh Review* of, I think, “Endymion,” played a part. They are both dead. One has gone through the narrow gate reserved for genius. The other may disport himself in the wide fields kept for the mugwump. It is not suggested that merit receives similar harsh treatment in your columns. The reverse is usually the case. But there is an *ex cathedra* atmosphere about the reviews in the *Journal*. It may be the fault of the reader, but it could be avoided entirely by an end of anonymity; and the name of the reviewer would increase or diminish the respect felt.—I am, etc.,

London. S.W.1.

E. GALLOP.

The London College of Osteopathy

SIR,—The advertisement in the *Lancet* to which Mr. W. E. Tucker (July 27, p. 141) calls attention raises an important question—what is the standing of the “London College of Osteopathy”? Leaving out any discussion on the theory or practice of osteopathy, I would remind any medical man who might be tempted to take advantage of the offer in the advertisement in the *Lancet* that the Select Committee of the House of Lords inquired very fully into the teaching of osteopathy in Britain, and found that the only existing establishment was the “British School of Osteopathy.” After an extensive examination of the claims made by the Dean of that school, the Committee stated: “The only existing establishment in this country for the education and examination of osteopaths was exposed, in the course of evidence before us, as being of negligible importance, inefficient for its purpose, and above all in thoroughly dishonest hands.”

No words could be stronger, and it is surely important to know if the “British School of Osteopathy,” which the Select Committee condemned, and the “London College of Osteopathy,” which the *Lancet* advertises, are one and the same. If not, has the “London College of Osteopathy” any better claim to be a teaching school?—I am, etc.,

London. W.1.

MORTON SMART.

Population Statistics in Palestine

SIR,—Dr. W. N. Leak's letter (July 20, p. 98) demonstrates what absurd conclusions can be derived from statistics when other important relevant data are not taken into account. His statistics showed that “in some parts of the country the (Arab) birth rate was no less than four times the death rate,” and the conclusion he naturally drew from his discovery was that “this rapid natural increase of the Arab population would certainly tax and probably overtax the resources of the country and lead

to scarcity and unrest." No account is taken of the primitive methods of land cultivation practised by Arabs; no consideration is given to the possibility of increasing the resources of the country by intensive cultivation of the soil made possible by the application of modern machinery and the use of water resources all previously undreamt of by the Arabs but now developed with such success by Jewish immigrants. Absorption of a portion of the population in industry, built up by Jewish enterprise, in the construction of roads, harbours, extension of the railway system, building, chemical works, etc., etc., is not even worthy of mention. No! The only conclusion drawn from his bare statistics on the political situation is that Jewish immigration, which has contributed most to the wealth of the country's economy, and has converted derelict waste land into fertile productive soil, must be stopped, because the Arabs might wrongly think that famine conditions, which might never arise, were due to Jewish immigration. I suppose Dr. Leak never thought of recommending another solution to check the phenomenal increase of the Arab population—i.e., the checking of Arab immigration from the adjoining territories of Syria and Transjordan? After all, Jewish immigrants have all been absorbed economically and do not breed as fast.—I am, etc.,

London, N.10.

I. S. Fox.

Colonial Medical Service

SIR,—I have followed the correspondence upon the conditions in the Service with much interest. A point that I do not think has been made sufficiently clear is that the Colonial Medical Service is not a service in any way comparable in organization with those of the Forces. The title connotes a very limited central control, by the Secretary of State, of the medical staffs of some 35 colonies and protectorates, varying from small islands to large territories, such as Nigeria; and a man entering the Service is in fact joining the staff of whichever territory he goes to, with its own local conditions of service. It therefore behoves him to choose his colony carefully.

Before the so-called unification of the Colonial Medical Service, certain colonies offered similar terms, and were grouped into such titles as the West African Medical Staff, East African Medical Service, Malayan Medical Service. Within each group salary scales, length of tours, retiring age, and pension rates, etc., were similar. The grouping still continues, though the titles are no longer valid. The advertisement for "His Majesty's Colonial Service" has recently been redrafted, probably as a result of the representation of the B.M.A., but in its new form (June 8, p. 9) it is still somewhat misleading. Senior members still smile at its attempt to paint a rosy picture. It states "... numerous posts are filled from within the Service for work in special branches . . .", and lower down, "There are large numbers of super-scale posts. . .". Candidates should appreciate that the "numerous posts" are in fact the super-scale ones for which he will be eligible, at the present rate of promotion, after approximately the fourteen years' service as a general field medical officer that "Ex-Africa" refers to (*Supplement*, June 1, p. 163).

The clinical side of the Service is of less importance to him than the administrative, and a young officer who has no special subject, or indeed possesses a higher qualification such as Membership, or D.A., is a positive embarrassment to his department, as all they want of a new arrival is that he will be a unit to post to an out-station in relief of another officer due for leave.

The Service history of an officer in one of the larger African colonies will illustrate the above. Joining with "Primary," he spent a tour as the only M.O. in an isolated station with little surgery. An application for study leave to complete the Fellowship was turned down. However, by devoting his entire normal six months' leave to work he obtained his F.R.C.S., the expenses and fees being borne by himself. He married and returned to duty. After a few months he was posted to a lonely military outpost where women were not permitted, and had perforce to send his wife "home." During his year there he performed one obligatory major operation. After thirteen years' service he was transferred as surgical specialist to another colony, where he served throughout the war years. Granted four months' leave in 1945 he applied for a period

of surgical rehabilitation, but was refused owing to "staffing difficulties" by his Government. Upon his return he appealed to the Colonial Office, but was informed that the Secretary of State could do nothing as he was bound by the wishes of local administration. Study leave, instead of being encouraged, is indeed rarely granted.

Speaking to a question recently in the House of Commons, Mr. Hall (as reported in the *Journal*) acknowledged that the terms for specialists were inadequate, but added that "he had recently made proposals to a number of Colonial Governments designed to remedy this defect. Some of the Governments had agreed to the proposals, others still had them under consideration"—a reply which demonstrates how unified the Colonial Medical Service is in fact.

"Another West Coast" (June 15, p. 931) is correct in advising the new entrant to concentrate on office work if he is to keep his eyes blue with medical headquarters. Accurate returns are more gratifying than the results of a clinical study. On the East Coast, senior medical officer and specialist are on the same salary, £1,100 per annum. The specialist, having chosen the professional side, has reached the highest he can go, but the S.M.O., whose work is mostly or entirely administrative, is still on the ladder to A.D.M.S., D.D.M.S., and finally D.M.S. up to a salary of £1,500 per annum. Transfers are becoming easier to obtain, but an officer offered promotion on transfer has to be very careful to keep within his "group" or he may find that he will have to serve five years longer than his previous agreement before being permitted to retire on a smaller pension than that to which he would have been entitled if he had remained where he was. It may thus pay him better to decline promotion.

The Colonial Medical Service will be a good career when it is truly unified, with uniform basic rates of pay for definite grades of officers throughout the Colonial Empire, terms of service being firmly controlled by the Secretary of State as they are in the Army, Navy, and Air Force.—I am, etc.,

"ANOTHER EAST COAST."

Re-education of Germany

SIR,—I, for one, am unable to muster up the faintest sympathy for the view expressed by Dr. Alexander Comfort (July 20, p. 104). If, during the coming quarter-century, the world is to avoid a third German aggression, the German people (physicians included) must have it ceaselessly dinned and drummed into them that they were the vanquished and not the victors; thus they may perhaps come to realize, at long last, that war does not pay. Enforcement of public recognition of our National Anthem is a very mild, but none the less a salutary, measure directed to this end.

At the risk of bruising Dr. Comfort's tender feelings, which are so very easily moved to "indignation," allow me to say that I rejoice to hear of firm action of this kind on the part of our forces of occupation; long may it be continued. As for the fear of dissipation of "accumulated goodwill," it seems that Dr. Comfort values German goodwill more highly than I do.—I am, etc.,

Cottingham.

NIGEL W. ROBERTS.

SIR,—Dr. Alexander Comfort (July 20, p. 104) takes upon himself to criticize, rather sweepingly, the sentence passed on a German doctor in the British zone who insulted our King by failing to pay that proper respect which should be shown at the playing of the National Anthem. He said that he did not know the German in question. Neither do I know Dr. Comfort. For my part, I was a soldier for six years and, my release notwithstanding, I continue to regard myself as such, and at the risk of offending Dr. Comfort's susceptibilities I feel bound to point out that I consider the sentence lenient.

Those of us who had the honour to be part of the original B.E.F., and who were thereafter made prisoner, had a perhaps exceptional opportunity of studying the German mind at closer quarters than were vouchsafed to others whose contact with the enemy was more remote. As such a one I consider that I am in a position to speak with some authority on questions related to the treatment of the German race.—I am, etc.,

CHARLES ILIFFE.

PHOLEDRINE

SULPHATE B.P.C.

IN SHOCK AND COLLAPSE

(*p*-hydroxy- β -methylamino-*n*-propylbenzene sulphate)

Pholedrine is an effective circulatory stimulant and restorative. In cases of shock and collapse the injection of pholedrine produces a rapid and sustained rise in blood pressure; its main indications thus lie in the treatment of conditions associated with a fall in blood-pressure, in the prevention and control of surgical shock, in circulatory failure and the acute heart failure following bronchial pneumonia, diphtheria, etc. Pholedrine for parental administration is available in ampoules of 1 c.c. (containing 0.02 gramme) in boxes of 6 and in bottles of 25 c.c. (each c.c. containing 0.02 gramme) and is obtainable from your usual suppliers.

PROGESTIN B.D.H. and ETHISTERONE B.D.H.

Progestin B.D.H. is identical with the natural hormone of the corpus luteum. It is administered by intramuscular injection in all conditions in which a rapid progestational response is required, particularly threatened and habitual abortion, menorrhagia and metrorrhagia. Minor degrees of luteal insufficiency may be corrected by oral administration of the synthetic analogue Ethisterone B.D.H. Further details are available on request.

Obituary

H. A. COLWELL, M.B., Ph.D., M.R.C.P., M.R.C.S., D.P.H.

Dr. H. A. Colwell died on July 22 at the age of 70. He was a medical scholar all his life, though he was for many years an executive medical officer in various capacities, and this scholarly attribute exhibited itself throughout his life in writing which reached a high level of distinction. His studentship at St. Bartholomew's Hospital showed Colwell to be a man well able to take all of the intellectual hurdles in front of him, and he qualified at London in 1900. A short spell of medical practice convinced him that his life's work was in other fields and he joined the staff of the cancer research laboratories of the Middlesex Hospital. His experimental work there with Prof. Russ was interrupted by war and the years 1916-18 found him serving in the R.A.M.C. as a major; he was a very valued officer for his all-round medical qualifications came into their own, and his knowledge of languages, both ancient and modern, allowed him to resolve many administrative difficulties on the spot. Enteric was rife in his district and he eventually became so ill that he was invalided to Malta for convalescence.

On returning to England he joined Robert Knox in radiotherapy at King's College Hospital, where eventually he was put in charge of the department. He resigned when he was about 60, and after that his leisure was devoted to writing, and it was during this period that his meticulous accuracy and wide knowledge were put at the service of the Oxford University Press. Colwell's medical writings may be said to begin with *Radium, X Rays and the Living Cell* (1915), written in collaboration with Russ. This book came at a time when it served the needs of the growing numbers of medical men and women entering the field of radiology. Colwell and Russ also collected the evidence of x-ray and radium damage since 1895, and in 1935 published *X-ray and Radium Injuries*. Colwell had an incisive pen at times, witness what he says on the subject of radium quackery. It was about the year 1935 that the unscrupulous were passing on to the public radio-active preparations to eat or drink or apply as beautifying agents. Colwell's comment was to the point: "One thing about such preparations is quite plain, if they are not radio-active as they claim to be they are fraudulent; if they fulfil that claim they are dangerous." He pleaded further that radio-active substances should be scheduled as poisons, but was careful to add that "it takes time to convince the legislative mind." His other writings include *An Introduction to the Study of X Rays and Radium* with Wakeley, and a very delightful contribution to quite another subject, *A History of Electrotherapy and Diagnosis*. His historical leanings were also shown in a memoir on Gideon Harvey.

He had a life-long interest in malignant disease; he served on the Council of the British Empire Cancer Campaign, and in 1935 was awarded the Garton Gold Medal and a prize of the British Empire Cancer Campaign for an essay on the "Biological Effects and Mode of Action of Radiations upon Malignant and Other Cells." Hector Colwell was a gifted man of rather retiring disposition; he was a beautiful pianist and no ordinary linguist. His friendships were few but were generally for life. His wife died in January of this year and he never recovered from this loss.

WILLIAM GEMMILL, Ch.M., F.R.C.S.

William Gemmill, joint professor of surgery in the University of Birmingham, died at his home at Edgbaston on July 28, almost at the moment of cessation of his active association with the University and with the staff of the United Hospital, Birmingham. He was appointed as assistant surgeon to the staff of the Queen's Hospital in 1920 and devoted himself for twenty-six years to the work of the Birmingham medical school, being appointed to the chair of surgery in 1932 on the death of Prof. William Billington. Born in Ayrshire, he trained at Edinburgh. He took the M.A. in 1901, graduated M.B., Ch.B. in 1905, and proceeded to the English F.R.C.S. in 1913, and finally to the Birmingham Ch.M. in 1933. In the

war of 1914-18 he was in charge of the surgical division of a general hospital in France. He had been a member of the B.M.A. for twenty-five years and was president of the Birmingham Branch from 1938 to 1943.

Gemmill was a man of great character and natural kindliness, with an outer crust of reserve and shyness which made him difficult to know. The more you knew him, however, the more he had to give, and his extensive practice in the Midlands was a tribute to the great personal esteem in which he was held by numerous practitioners and past students. He was a general surgeon in the best meaning of that term, with a broad basic knowledge of surgery and a wide experience in many fields. The war to some extent diverted his early training, and whilst it gave him a broad outlook, which only war can give, it probably prevented his specialized training in neurosurgery, in which he was always deeply interested. As a teacher he was at his best at the bedside, where his methodical examination, his acumen in grasping the salient points in a case, and his power of securing the confidence and co-operation of the patient gave his dressers a clinical lesson which they never forgot. He was wholly absorbed in his work and his patients and put himself so unreservedly at the call of practice that he found little time for writing or recreation. An annual holiday in his homeland, one felt, was for him something in the nature of a pilgrimage and to the last his dream was of retiring there—a dream to remain unfulfilled owing to his untimely death.

S. G. B.

Dr. T. DOUGLAS BROWN, a member of the British Medical Association for fifty years, died on July 17 at Bournemouth. He received his medical education at Glasgow, graduating M.B., C.M. in 1894. In 1904 he proceeded M.D. of Glasgow University, and he worked in Glasgow until 1914. During the war of 1914-18 he served as a Territorial medical officer, first as a captain, R.A.M.C., attached to the 9th H.L.I., and later as a major, and second-in-command of a field ambulance, and subsequently he was in charge of the Cambuslang and finally the Yorkhill military hospitals. On demobilization he settled in Bournemouth. His personal kindliness and sympathy, added to his professional knowledge and skill, soon made him one of the best-known medical practitioners in the area. In spite of a long illness, which he bore with great patience and fortitude, he continued to practise right up to a few weeks before his death. He was a fine practitioner, and through all his fifty years of practice he kept abreast of modern developments in medicine. He had a keen sense of humour and a kindly, gentle manner which endeared him to a large circle of patients and friends, who now mourn his loss. His widow helped and comforted him through the long period of illness and increasing weakness, and now has the sympathy of all who knew and loved him.

Dr. GEORGE MACKIE died on July 20 after several months of illness. He studied at Edinburgh, taking the M.B. in 1899 and the M.D. in 1922. He came to Malvern in 1902 as assistant to the late Dr. Brockatt, and immediately plunged into very busy practice, including attendance on the boys at Malvern College and the pupils of several well-known schools. During the war of 1914-18 he served in France in the R.A.M.C. with the rank of lieutenant-colonel, and was three times mentioned in despatches and received the D.S.O. In 1921 he received the Territorial Decoration. After an absence of ten years he returned to Malvern and again took up general practice. As County Director of the British Red Cross Society he gave of his best to that work in Worcestershire, and during the recent war was responsible for the organization and administration of the Worcestershire convalescent hospitals. In 1944 he was awarded the O.B.E. (Military Division) for his work in connexion with the Home Guard medical services in the county. Dr. Mackie was a man of many interests, and his ideas for the development of Malvern into a health centre for sufferers from rheumatic and cardiac complaints revealed imaginative and creative ability of the highest order. He will be missed by a wide circle of patients and friends, whose sympathy will go out to his widow, son, and daughter.

GEORGE RONALD PYM ALDRED-BROWN died suddenly at his home in Bath on July 26. He was 49 years of age, and by his untimely death Bath loses yet another of her young consultants. He was educated at Harrow and Keble College, Oxford, where he took his B.A.; he graduated M.B., B.Ch. at the London

Hospital in 1924. In 1938 he took his M.D. degree at Oxford. Aldred-Brown had served for three years in the 1914-18 war, as a captain in the Royal Field Artillery, and during this time the seeds of his illness were sown. He came to Bath from Dorset, where he had held the post of physician, pathologist, and bacteriologist at the Dorset County Hospital. In 1930 he was elected honorary physician to the Royal National Hospital for Rheumatic Diseases. In due course he became senior physician and chairman of the medical board. The war upset all the plans for the building of a new hospital, and was a keen disappointment to Aldred-Brown, who had worked so hard to make the project a success.

During the war years the staff of the hospital was greatly depleted, but in spite of physical disability Aldred-Brown carried on, and indeed will be remembered by many for the manner in which he planned and achieved the present rehabilitation and remedial therapy department. In 1945, after fifteen years' service to the hospital, he was elected an honorary consulting physician. Aldred-Brown was widely known for his interest in rheumatism and was chairman of the Bath International Conference on Rheumatic Diseases in 1938. He was a member of the International Society of Medical Hydrology and of the International League against Rheumatism. He contributed several papers to the more specialized journals. He was a keen golfer and tennis player. Aldred-Brown will be sadly missed by his patients and medical colleagues.

The Services

The Efficiency Decoration of the Territorial Army has been conferred upon the following officers: Lieut.-Col. (Temp. Brig.) A. A. Egger (T.A.R.O.), Major (Temp. Lieut.-Col.), J. V. Bradley, Hon. Major J. N. Martin, and Majors T. T. S. Hall, M.B.E., W. L. Kinneer, M.B.E., and W. G. Platt, R.A.M.C.

The following appointments and mentions in dispatches have been announced in recognition of gallant and distinguished services in Malaya in 1942.

C.B.E. (Military Division).—Brig. (Temp.) C. H. Stringer, D.S.O., O.B.E., late R.A.M.C.

O.B.E. (Military Division).—Lieut.-Col. D. C. Chopra, I.M.S. (since died).

M.B.E. (Military Division).—Major (Temp.) C. W. Maisey, R.A.M.C.

Mentioned in Dispatches.—Brig. (Temp.) C. D. K. Seaver, and Col. E. Percival, D.S.O., M.C., and V. H. Wardle, M.C., T.D., late R.A.M.C., Brig. (Acting) D. S. Middleton, Col. (Temp.) J. Bennet, Col. (Acting) J. Taylor, O.B.E., Lieut.-Col. J. W. Craven, M.C., T.D., Lieut.-Col. (Temp.) W. G. Harvey, Major (Temp.) H. M. S. G. Beadnell, M.B.E., Majors (Acting) P. R. Graves, M.B.E., and H. Henderson, Capt. J. E. A. Bartlett, M. H. Churchill, T. R. S. Cormack, E. K. Cruikshank, J. G. Jesson, J. A. Mark, W. H. McDonald, T. B. Smiley, M.C., and R. B. C. Welsh, R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Died at Sea.—Surg. Lieut. Ian Mackenzie, R.N.V.R.

Died at Sea.—Capt. James McAllister, R.A.M.C.

Died in India.—Lieut.-Col. Michael Henry Wace, I.A.M.C.

DOMVILLE MEMORIAL GIFT

Trustees wish to elect, on or about Sept. 18, a recipient of the Gove Gift, the present value of which is £7 yearly, tenable for three years. The recipient must be a child of a deceased naval medical officer, in necessitous circumstances and under 15 years of age. Particulars of claims, with birth certificates, must reach the honorary secretary, Domville Memorial Gift, Haslar Hospital, Gosport, Hants, by Sept. 12. Further information regarding the Gift may be obtained from the same address.

NORTH PERSIAN FORCES MEMORIAL

The War Office announces that the North Persian Forces Memorial Medal will be awarded again next year after a lapse of nine years. This memorial was founded in 1923 by officers of the R.A.M.C. and the I.M.S. who served with the North Persian Forces during the war of 1914-18 to commemorate the services of those forces and to encourage the study of tropical medicine and tropical hygiene. The memorial takes the form of a silver medal and is awarded annually for the best paper by a single author on tropical medicine or tropical hygiene published in any journal during the twelve months ending Dec. 31 by any medical officer of under twelve years' service in the R.N., R.A.M.C., R.A.F., I.M.S., or the Colonial Medical

Service. Only officers on a regular or short service engagement in the R.A.M.C., R.A.F., and I.M.S. are eligible for the award. The award is announced in the latter part of the year following that in which the paper was published, provided that the memorial committee consider the paper to have attained the standard of merit justifying the award.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on July 27, the following degrees were conferred:

D.M.—C. W. Hope-Gill, R. C. Browne.
M.Ch.—S. F. Taylor.
B.M.—B.Cit.—G. N. Chandler, D. H. Brooks, J. N. Cozens-Hardy, R. H. Hardy, P. L. Pickering, J. M. K. Spalding, J. L. Hadley, P. S. Brown, B. McConkey, H. L. Backhouse, G. A. K. Missen, Margaret Lingard, Jean C. Ritchie, H. J. F. Cairns, P. M. de C. Williams, L. T. Cotton, A. G. Hayler, P. R. Clay, Gert L. Loewi, Diana Geekie, Marianne E. Rooih.
*In absence.

UNIVERSITY OF LONDON

William Charles Wallace Nixon, M.D., F.R.C.S., F.R.C.O.G., has been appointed to the University Chair of Obstetrics and Gynaecology tenable at University College Hospital Medical School as from Oct. 1.

Ronald Hare, M.D., has been appointed to the University Chair of Bacteriology tenable at St. Thomas's Hospital Medical School as from Oct. 1.

The title of Professor of Physiology in the University has been conferred on Walter Roworth Spurrell, M.S., F.R.C.S., in respect of the post held by him at Guy's Hospital Medical School.

The title of Professor of Clinical Pathology in the University has been conferred on Robert James Valentine Pulvertaft, M.D., F.R.C.P., in respect of the post held by him at Westminster Hospital Medical School.

The title of Reader in Pathology in the University has been conferred on Sigiberto Jose De Navasquez, M.D., in respect of the post held by him at Guy's Hospital Medical School.

The following candidates have been approved at the examinations indicated:

M.D.—*Branch I (Medicine)*: B. F. Gans, A. J. Glazebrook, W. W. Gooddy, J. F. Goodwin, P. Harvey, C. F. Hawkins, J. C. Houston, M. E. MacGregor, J. D. N. Nabarro, C. S. Nicol, D. W. Pugh, R. D. Tonkin, J. R. Trounce, B. G. Wells (gold medal), D. A. J. Williamson. *Branch II (Pathology)*: H. Caplin, G. D. Lumb, J. A. H. Wylie. *Branch III (Psychological Medicine)*: A. M. Edwards, P. H. Tooley. *Branch IV (Midwifery and Diseases of Women)*: Ursula M. Lisler. *Branch V (Gynaecology)*: G. H. Taylor, J. Watkins-Pitchford. *Branch VI (Tropical Medicine)*: M. S. Branson. *Branch IV (Laryngology, Otolaryngology, and Rhinology)*: C. McK. Johnston, J. B. Musgrove.

UNIVERSITY OF WALES

The following candidates at the Welsh National School of Medicine have satisfied the examiners at the examinations indicated:

M.B., B.Ch.—*Pharmacology*: Maureen M. Bassett, C. H. Burman, Sarah A. Chard, A. V. Coleman, D. P. Davies, G. J. Davies, F. J. Davis, Joan V. Davis, E. F. Griffiths, E. J. Hargadon, J. M. E. Hyde, E. G. A. Jackson, Marjorie L. James, J. H. Jones, T. D. Jones, D. M. D. King, Doreen M. R. Lewis, R. H. Lewis, C. S. Livingstone, Joan A. McLay, J. E. Mitchell, Lillian M. Morgan, M. A. Owen, D. Si. J. D. Rees, G. M. Reynolds, Frances M. Richards, J. M. Richards, Esme S. Rogers, Sybil H. Stephens, C. E. Stroud, Augusta J. Taylor, G. Thomas, J. D. Thomas, J. H. S. Wakella, J. A. Wilkinson. *Pathology and Bacteriology*: A. J. Dark, Marjorie J. A. Davies, D. W. John, H. E. Jones, Margaret O. Jones, Rosina E. Jones, J. G. Leopold. *Medicine*: G. E. Davies, Margaret E. Davies, Gwenllian M. Griffith, S. T. James, A. S. Jones, Mary Lawrence, R. Medicoit, Jean T. Smith, J. G. Tomkins. *Surgery*: T. J. Anthony, Norah C. Curran, C. H. L. Howells, Eluned K. Jones, H. T. Jones, Nest Jones, F. I. Powell, Myfanwy M. G. Prethero, B. F. Richards, Prudence K. Roberts, Mary Smith, Heather Stockdale, T. M. Warren, K. P. Williams. *Obstetrics and Gynaecology*: D. R. Bowen, Joan P. Ciantar, A. C. Coulthard, G. C. Davies, Janet Dean-Jones, G. S. Foster, C. Harvard, D. W. James, Margaret E. B. Jones, W. R. King, J. B. R. Lewis, L. T. Lewis, Constance A. M. Llewellyn, Margaret L. Morgan, Vivien J. Parker, L. T. Rees, G. G. Richmond, S. Solomon.
*With distinction.

UNIVERSITY OF DUBLIN

On July 3 the degree of Litt.D. (Stip. Cond.) was conferred on James Johnston Abraham, C.B.E., D.S.O., M.D., F.R.C.S., consulting surgeon to Princess Beatrice Hospital, London, S.W.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a quarterly comitia of the College, held on July 25, with the President, Lord Moran, in the chair, the following were elected officers for the ensuing year: *Censors*, G. E. S. Ward, E. B. Smith, W. Johnson; *Sir Adolphe Abrahams*; *Treasurer*, W. G. Barnard; *Registrar*, H. E. A. Boldero; *Assistant Registrar*, W. D. W. Brooks. The Registrar announced that Jacob David Judah was awarded the Murchison Scholarship for 1946. Dr. W. E. Hume was elected the representative of the College on the Council of King's College,

University of Durham. Dr. C. E. Lakin was appointed Harveian Orator and Dr. Janet Vaughan Bradshaw Lecturer, both for 1947. The following Lecturers for 1947 were also appointed: *Goulstonian*, Dr. F. Avery Jones; *Lumleian*, Dr. J. P. Martin; *Oliver-Sharpey*, Prof. F. C. Bartlett; *FitzPatrick*, Sir Arthur MacNalty; *Lloyd Roberts*, Mr. Harold Nicholson; *Humphry Davy Rolleston*, Dr. P. C. P. Cloake.

The following, having satisfied the Censors' Board, were elected Members of the College:

R. Al-Mankabadi, M.B., C. D. Anderson, M.B., D. A. P. Anderson, M.B., Abd-el-Hamid A. A. Aia, M.B., D. A. Ballantyne, M.B., H. S. Barber, M.D., G. Behr, L.R.C.P., R. C. S. Benson, M.B., T. S. L. Beswick, M.B., D. W. Beynon, M.B., E. J. Blair, M.D., Anne Bolton, M.B., N. R. Butler, M.B., J. E. Cates, M.D., F. E. de W. Cayley, L.R.C.P., M. Chittiers, M.B., J. W. C. Cochrane, M.D., W. H. R. Cook, M.B., I. S. Dalton, M.B., H. E. De Wardener, M.B., R. C. S. Dick, M.B., H. Droller, M.D., Margaret E. Edmunds, M.B., A. C. Eilthorn, M.B., G. R. Fryers, M.B., W. R. Gauld, M.D., J. A. L. Gilbert, M.B., A. Guedatarián, L.R.C.P., M. Hamilton, M.B., J. B. Heycock, L.R.C.P., G. E. Hosking, M.B., C. A. Houlder, M.B., A. M. Jelliffe, M.B., E. S. Jones, M.B., J. D. O. Kerr, M.B., P. D. C. Kinmont, M.B., S. C. Kusumgar, M.B., J. W. Lacey, M.D., D. R. Laurence, M.B., E. Leigh, M.D., D. C. Lewin, M.B., L. A. Liversedge, M.D., G. Lorrain, M.B., Flying Officer B. H. McCracken, M.D., R.A.F.V.R., A. J. S. McFadden, M.B., F. McL. McGown, M.B., Surg. Lieut. G. MacGregor, M.B., R.N.V.R., K. S. MacLean, M.B., Mary L. Muell, M.B., J. H. Moseley, M.B., B. Moshal, M.D., Major P. B. L. Muldoon, M.B., R.A.M.C., G. R. E. Taylor, M.B., C. S. Nicol, M.B., J. C. R. Nuttall-Smith, M.B., A. B. Pollard, M.B., M. B. W. Powell, M.B., Capt. S. B. Rampling, M.B., R.A.M.C., T. L. Reeves, M.B., F. Robertson, M.D., G. R. Royston, M.D., K. J. Samson, M.D., R. Semple, M.B., N. M. Shah, M.D., Sheila Sheehan, M.B., J. R. Sinton, M.B., J. B. Sloane, M.B., D. Stafford-Clark, M.B., R. P. Strat, L.R.C.P., J. A. Strong, M.B., H. J. C. Swan, M.B., N. G. Talwalkar, M.D., P. E. R. Tattersall, M.B., D. C. Thursby-Felham, L.R.C.P., H. Ulrich, M.B., G. C. Wells, M.B., D. A. J. Williamson, M.B., B. D. R. Wilson, M.B., C. Wilson, D.M.

Licences to practise were conferred upon 118 candidates (including 27 women) who had passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board and who have complied with the necessary by-laws:

A. R. L. Abel, Davida M. Adams, D. M. C. Ainscow, E. J. Allaway, Barbara M. Ansell, Constance M. A. Bahtin, M. E. Bailey, S. Balfour-Lynn, Joan A. Barrett, H. D. Beckett, E. I. Bieber, D. Bigley, D. K. Briggs, R. H. Broughion, H. Caplan, V. L. Cartledge, D. M. T. Cones, P. D. Crosbie, A. M. Davies, P. R. Davis, R. C. Davison, Rosemary Dearden, Mary M. Dickinson, Romola D. Dunsmore, D. R. Edwards, H. E. Foulkes, G. H. Fisher, D. P. Fitzgerald, I. Fletcher, Frances M. Fountain, R. O. J. Fry, J. D. Fuller, B. D. Grant, Dora Green, H. G. Griffin, I. R. Haire, P. H. T. Hall, F. A. E. Hamilton, G. J. L. Hamilton, R. E. Handforth, J. J. Hopkinson, R. J. Howat, Edna C. Howe, G. Hughes, G. C. Hunter, I. Jackson, P. D. C. Jackson, T. Jackson, Glyndwr Jeffreys, N. B. Jemalan, E. John, J. W. G. Johnson, Catherine M. E. Jones, C. W. I. Jones, D. W. Jones, I. S. M. Jones, Thelma D. Jørgensen, R. S. Kagan, R. C. Keane, G. W. Korn, Marjorie A. C. Kuck, T. D. Lambert, Gertrude Latner, K. Lawrence, R. M. H. Layland, M. B. Lennard, C. Levin, T. L. T. Lewis, R. I. T. Lindsay, Janet G. S. McDowall, E. P. Mackenzie, H. H. Margulies, Margaret A. Marten, T. C. H. Mathews, Gladys A. Meigh, G. S. Metters, J. R. Mikhael, Kate H. Miller, P. R. Miller, J. B. Moore, N. S. Moores, Marguerite F. E. Morford, C. P. Newcombe, W. Nixon, J. A. Noblett, L. W. Oxenham, J. Parkyn, J. Pavey-Smith, B. W. Perlow, J. I. Pugh, R. J. Randall, H. M. Rayner, G. A. Readett, R. Renwick, Beatrice E. S. Richards, J. P. R. Richardson, J. F. S. Robertson, K. W. Robinson, H. E. Robson, P. N. Robson, Rosemary J. M. Rose, B. L. L. Rygate, Jutta Scharfstein, D. Seymour, B. E. Shaipr, Dorothy M. Silvester, Patricia M. Stanwell, K. D. Stewart, Janet Sutherland, C. K. M. Thacker, Joan M. H. Thomas, J. Thompson, P. Timmis, L. Walkden, R. W. W. Watson, P. E. Webb, A. A. Weyman, J. L. Whitmore.

Diplomas in Public Health were granted, jointly with the Royal College of Surgeons of England, to the following successful candidates:

J. Besson, Phoebe Charlton, B. A. Coghlan, R. V. Coxon, Enid G. M. Cummings, H. S. Fraser, S. MacL. Fraser, A. A. Huse, J. P. Kennedy, A. A. Lewis, G. L. McLeod, Mary N. MacQ. Paulin, Mary Roland, R. G. Samuel, E. L. Tee, R. L. Worrall.

Diplomas in Anaesthetics were granted, jointly with the Royal College of Surgeons of England, to the successful candidates whose names were published in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of July 6 (p. 29). Diplomas in Laryngology and Otolaryngology, in Psychological Medicine, and in Tropical Medicine and Hygiene were granted, jointly with the Royal College of Surgeons of England, to the successful candidates whose names were published in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of July 27 (p. 143).

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council, held on Aug. 1, with Sir Alfred Webb-Johnson, Bt., President, in the chair, Prof. G. Grey Turner was re-appointed as representative of the College on the Council of King's College, Newcastle-upon-Tyne, for a further period of three years. A gift of a silver bowl was received from Mr. W. E. Tanner. The thanks of the Council for assistance in the preservation and development of the Museum were given to Sir James Walton, Mr. Warren R. Dawson, and Prof. F. Wood Jones. Mr. I. Carnac Rivett was invited to attend meetings of the Council during the ensuing year as the representative of gynaecology and obstetrics.

Diplomas of Membership and Diplomas in Public Health were granted, jointly with the Royal College of Physicians of London, to the successful candidates whose names were printed in the report of the meeting of the Royal College of Physicians of London. (See list above.)

Medical News

The trustees of the Leverhulme Research Fellowships have approved the award of a grant to E. H. F. Baldwin, B.A., Ph.D., lecturer in biochemistry in the University of Cambridge, for research into the comparative biochemistry of nitrogen metabolism. Application forms for Fellowships and Research Grants may be obtained from the secretary of the Fellowships, 7, Bedford Row, London, W.C.1.

Lord Moran has been re-elected President of the National Federation of Personal Health Associations; Dr. John Hall, of Liverpool, chairman; and Mr. T. Crew, Leicester, hon. secretary.

EPIDEMIOLOGICAL NOTES

Typhoid Epidemic

The number of cases in the typhoid epidemic at Aberystwyth continues to increase. It was suggested in our account of August 10 (p. 206) that there were likely to be more cases at Aberystwyth and at other parts of the country in returning holiday-makers. Up to August 13 notifications had increased to 110, and there had been two fatal cases—one at Aberystwyth, and another at Llanelly. Cases infected at Aberystwyth, apparently on July 11, by ice-cream contaminated by the typhoid carrier who made it and sold it have now been reported from Northampton (5), Birmingham (5), Oldbury, Worcestershire (3), Manchester (2); at Shavington, near Crewe, and at Ilford, Essex, and other towns single cases have appeared. It seems likely that cases will continue to appear but with diminishing frequency at Aberystwyth and elsewhere.

The most heavily infected portions of ice-cream were consumed by local inhabitants attending church excursions and a youth rally and were not available on a large scale to the ordinary holiday-makers. The infection is of moderate severity only, but more deaths are expected. The suspected carrier is a urinary excretor. Up to the present *Bact. typhosum* has not been found in his stools after four examinations. The organism recovered from his urine belongs to Vi-bacteriophage Type C. Organisms of the same type have been identified from several of the patients.

Uncooked shellfish are said to have caused 8 cases of typhoid at Glasgow and 4 (one fatal) at Dublin.

Detection of Typhoid Carriers

The *Monthly Bulletin of the Ministry of Health and the Emergency Public Health Laboratory Service* (1945, 4, 224) contained a note on the detection of typhoid carriers. It is estimated that in 5% of cases of typhoid a raised titre of Vi-agglutinins persists for six months or more, and that 2% or more of patients become chronic carriers. Nine out of ten of the latter have permanently elevated Vi-agglutinin titres. The measurement of Vi-antibody is therefore a valuable indication of the carrier state.

"A chronic carrier may cease to excrete typhoid bacilli for no apparent reason and may resume doing so without any detectable alteration in his well-being. Epidemiological evidence, although not conclusive, suggests that the intervals of freedom may last for months or even years, but the Vi-agglutination test remains positive during these intervals. It is not proposed that any control, other than that afforded by the Public Health (Infectious Diseases) Regulations, 1927, should be exercised over carriers, and in this connexion the attention of medical officers of health is called to pp. 58-60 of the annual report for 1932 of the Chief Medical Officer of the Ministry.

"The method of detection is, before discharge from hospitals every typhoid convalescent should have a blood test for Vi-agglutinins. If they are absent no further action need be taken. If present (as might be expected in about one-half of the cases) a second test should be made three months later, when, if they are no longer present, nothing further need be done. If, however, Vi-agglutinins are present in a titre as high as, or higher than, before, two examinations a week for three weeks of the stools and urine, or, failing this, six examinations with as long an interval as possible between, should be made by selective cultural methods to find out whether typhoid bacilli are being excreted. If they are, the patient should be regarded as a persistent carrier; if they are not, it might be advisable to repeat the Vi-agglutination test three months later to see whether the titre is falling. Further action would depend on circumstances.

"As every case of typhoid fever owes its origin to a carrier (shedder) it is an obvious advantage to a medical officer of health to know at least some of the potential sources of infection in his district. By ascertaining the type of infecting

organism by the Vi-bacteriophage method, and by keeping a register of the names and addresses of the carriers thus typed, it may prove easier to trace the source of infection of fresh cases when they arise. The Emergency Public Health laboratories have been requested to do all they can to assist medical officers of health in making the proposals effective."

Heat-treatment of Ice-cream Mix

Draft regulations for the compulsory heat-treatment of ice-cream mix have been framed by the Minister of Health and circulated to various bodies for consideration, but no date has yet been fixed for bringing them into operation. Heat-treatment, it is proposed, shall not be necessary when ice-cream is made from a "complete cold mix powder" which is reconstituted with drinking-water and is frozen within one hour of reconstitution, but in other cases after the mix has been reduced to liquid form it must not be kept for more than one hour before being heated to 150° F. (65.5° C.) for thirty minutes or to 160° F. (71.1° C.) for ten minutes. The mix must then be cooled to 45° F. (7.2° C.) within ninety minutes and held at that temperature until frozen. The finished ice-cream must be stored at not more than 28° F. (-2° C.).

Anterior Poliomyelitis

There have now been 7 notifications from the Potters Bar area of Middlesex; the first of these cases, all in children, appeared on July 1.

High Barnet has had 6 cases over the last three weeks, 4 adults and 2 children, and 1 of the male patients has reached the stage of respiratory paralysis.

East Barnet has had 5 cases over the last five weeks, 4 children and 1 adult. In the first case the only sign at onset was paralysis of the soft palate. The most recent case, in a male adult, was a neurotic with a mild pyrexia admitted for general and neurological investigation. The diagnosis, which had not been suspected, was made only after a routine lumbar puncture.

Notifications in England and Wales during the six weeks ending Aug. 3, 1946, were 8, 9, 12, 10, 18, and 23. In the corresponding weeks of 1945 they were 8, 15, 12, 16, 22, and 21, respectively, and the upward trend expresses the usual seasonal rise. During the past week single cases have been diagnosed at Malden and Coombe Borough, Sutton and Cheam Borough, and Merton and Morden U.D. These figures are not unusual at this time of the year.

There have been more cases of poliomyelitis in the U.S.A. during the present year than in any year since 1934. Of the 380 patients in Minneapolis, Minnesota, 10% have died, and the incidence of the disease has risen sharply in ten other States.

At Dijon and nearby towns 15 cases of poliomyelitis have been reported recently.

Discussion of Table

In England and Wales a large increase in the notifications of diphtheria—61 cases—was recorded. Other large variations in incidence were increases in scarlet fever 58, and dysentery 30, and a decrease in measles 42.

The increase in cases of diphtheria in Lancashire 37 was mainly contributed by the county boroughs. There were 32 more notifications of scarlet fever also in Lancashire, and 22 more in Yorkshire West Riding. Although the total notifications of whooping-cough were 6 fewer than in the preceding week, there were considerable variations in local trends—increases in Lancashire West Riding 50 and Lancashire 32, and a decrease in Kent 35. The number of cases of measles rose in Lancashire 121 and Durham 46, and decreased in Surrey 64 and Middlesex 63. The rise in the incidence of dysentery was mainly due to the experience of London, where the cases rose from 4 to 27 (St. Pancras 14).

In Scotland very little change occurred in the returns of infectious diseases; there were fewer cases of acute primary pneumonia 15 and scarlet fever 12, and a rise of 7 in the notifications of diphtheria.

In Eire there was a rise in the incidence of diphtheria 7 and of enteritis and diarrhoea 7, with a fall in the returns for measles 12 and scarlet fever 15.

In Northern Ireland a decrease of 10 was reported in the figures for both diphtheria and whooping-cough.

Week Ending August 3

The notifications of infectious diseases during the week in England and Wales included: scarlet fever 940, whooping-cough 2,092, diphtheria 246, measles 3,540, acute pneumonia 356, cerebrospinal fever 44, dysentery 59, acute poliomyelitis 23, paratyphoid 7, typhoid 60.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 27

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

ANY QUESTIONS?

Removal of Tattoo Marks

Q.—*What is the best way to remove tattoo marks?*

A.—The question of removal of identifying marks from the criminal has been discussed in medico-legal textbooks. There is no effective procedure except surgical treatment, although it is sometimes sufficient to change an inappropriate design by additional tattooing. The question has also been considered in connexion with the marks—for instance, on the face—from the admission of particles following motor accidents. Here plastic surgery may be required.

Treatment of Phlebitis

Q.—(i) *What are the modern treatment of phlebitis and its rationale? All the older textbooks advise immobilization for periods up to four weeks and stress the dangers of embolus. More recently there is a tendency to encourage early active movement in such conditions as phlegmasia alba dolens. A patient recently had a recurrence of phlebitis in the internal saphenous vein, beginning below the knee and spreading up into the thigh. It was advised that the limb be kept wrapped in a dressing of kaolin poultice and that the patient (a farmer) continue his normal activities. This seems so much the opposite of immobilization between sandbags for four weeks that I should be glad of an opinion as to the safety of the treatment and the probable period of incapacity.*

(ii) *An intelligent patient always demands an explanation. What is the modern view on aetiology in the absence of a history of typhoid, pregnancy, operation, varicose veins, trauma, or a streptococcal throat infection?*

A.—(i) For practical purposes "phlebitis" usually means a pathological process occurring in superficial veins of the lower limb, and in veins that are incompetent and varicose. There are naturally many other types, but their incidence is small when compared to the varicose type. The consensus is now in favour of ambulatory treatment in the majority of cases. The limb is enclosed in an adhesive bandage to well above the upper limit of the phlebitis. Moderate activity is allowed, and the supporting bandage is changed at intervals of about a week. When all pain, tenderness, and redness have gone the temporary use of a crêpe bandage is advisable before allowing unrestricted use of the limb. Ultimately treatment directed to the varicose veins themselves may be necessary—either injections or operation; but injections should never be carried out until at least six months have elapsed after an attack of phlebitis. This supporting treatment during phlebitis lessens pain, diminishes oedema, and therefore favours repair processes, and the moderate use of the limb improves the venous circulation and so lessens the risk of extension of the thrombosis. Clinical experience has shown the safety of this method. The local thrombus is adherent to the vein wall at the site of impaired nutrition, it is very irregular in shape, and the vein itself on the heart side is usually also irregular. Pulmonary emboli tend to come from extensions from the original thrombus of clot which is no longer adherent to the vessel wall. Bed may certainly lessen the risk of separation of a thrombus, but it will certainly favour the extension of thrombosis as the result of stagnation. In the case now quoted the recurrent phlebitis was probably associated with veins that were incompetent but un-

diagnosed as such, and therefore the treatment by support, as advised, was correct. Ambulatory treatment is not advisable where there is thrombosis of massive type in a completely incompetent internal saphenous vein, and ligation at the saphenous opening may be preferable in these. Neither does the treatment apply to those cases of infectious or bacterial thrombophlebitis associated with high fever. In most cases the period of relative incapacity due to phlebitis is determined by the extent of the process when the patient comes under observation, and it usually varies from three to six weeks. On the other hand, almost all clinicians still favour a prolonged period of immobility in conditions of deep thrombosis or phlegmasia alba dolens. In such cases the clot is massive, the veins are not irregular, the walls are healthy, and the thrombus is but lightly adherent.

(ii) Phlebitis in superficial veins in the lower limbs is almost always secondary to incompetence and varicosity. The thrombosis occurs at the site of thinning and impaired nutrition of the vein wall, and results from stagnation. At the local site the initial clot is adherent and irregular. Focal infection may play a part, but if it were an important part one would expect phlebitis to be much commoner in healthy, competent veins and in other situations. In a large number of cases this venous incompetence is overlooked. The phlebitis associated with typhoid, the puerperium, and operation is usually a deep thrombosis. Trauma or focal infection is more likely to lead to thrombosis in a varicose vein than in a normal one.

Diet and Renal Calculus

Q.—*A man of 46 with only one kidney (the other was removed in 1918) has twice had a renal calculus—one in 1933 and another last year. Cystoscopy and retrograde pyelography showed nothing abnormal, but the second stone was formed of oxalates. Both stones were passed "per vias naturales." What advice should be given—as to diet, for example—to prevent another stone forming?*

A.—The advice to avoid strawberries, rhubarb, spinach, and tomatoes is so well known that it does not merit repetition. However, it must be acknowledged that patients who never eat these substances form oxalate stones, and on seeking for the cause we are thrown back on to the statement that "gastro-intestinal upsets" can give rise to oxaluria. If this statement is analysed fully it seems most probable that the underlying cause of this alimentary upset is excess of carbohydrate in the diet, and patients who suffer from oxaluria should be advised to limit their carbohydrate intake.

Achondroplasia

Q.—*A patient aged 2 has achondroplasia. Has pituitary growth hormone any effect on the course of this disease? If so, what are the dosage and the period of treatment? Is there any danger in its prolonged use?*

A.—Achondroplasia is a congenital abnormality of bone cartilage formation arising in foetal life, and characterized by short legs and arms, a relatively long body, good intelligence, a big head and face, a square nose with a depressed bridge, and spade-like hands. Underlying endocrine defects have not been discovered, and in the writer's opinion this condition is unlikely to prove of endocrine origin or to be influenced fundamentally by endocrine therapy.

As regards the general question of the use of pituitary growth hormone, there is no danger from prolonged use. As, however, antibodies form in the blood after some weeks of injection it is advisable to separate the courses of treatment by intervals of two months. Even in dwarfism specifically due to a pituitary deficiency the writer is not impressed by the clinical results of the pituitary growth hormone, or at any rate by those preparations available to clinicians up to the present time.

Nail-biting in Adults

Q.—*What is the cure for adult nail-biting?*

A.—Nail-biting is in most cases the result of suppressed aggressiveness. It usually originates in early childhood, when the child, thwarted in every way and finding no other outlet, expresses it in this manner. Biting is fundamentally an aggressive rather than a nutritional form of behaviour; and biting

one's nails has the advantage over biting other things, in that one can feel the effect of the biting on oneself. It often occurs in moments of tension, such as during an examination. Exertion of will may be effective, but difficult because it is opposed by the basic and natural impulse to assert oneself. Only a very strong incentive to the exercise of the will is capable of overcoming the habit.

The natural cure is greater expression for normal assertive tendencies in life, work, and in relation to people; but the difficulty in this as in all the psychoneuroses is that it is no longer circumstances which thwart one but oneself. So that instructions to be more assertive in normal ways may be met by inhibitions in the patient himself, who, because of the early fears which made him repress his assertiveness, dare not express it now. The only adequate method, therefore, is by psychological treatment to discover the cause of the original aggressiveness and of its repression, and so release it for the normal uses of life.

Formates in Sweat and Urine

Q.—What is the hydrogen formate content of spirit of formic acid? It is stated in a dictionary of chemistry that formic acid appears in sweat and urine. Is this true? If so, is formic acid present in excess in the acid sweats of rheumatism?

A.—Spirit of formic acid is probably another name for spiritus formicarum. This contains 1% of formic acid in about 70% alcohol. It was formerly obtained by macerating ants. Formates appear in the urine, the normal daily excretion being 30 to 120 mg. Some part of this formate may be present as formic acid, but this is not known. Since formates appear in urine, they will almost certainly be present in sweat. It is not known whether formic acid is present in excess in the acid sweats of rheumatism.

Face-powder Dermatitis

Q.—A patient suffers from an acute erythematous dermatitis of the face starting about two hours after applying face powder—the condition becoming progressively worse in the next 24–36 hours. It appeared first about eight months ago, and sensitization must have taken place when face powder was used when the patient had a boil on the face. A so-called non-irritant powder has had the same effect. What are the constituents of face powder likely to cause such a reaction? Could it be due to the scent? Is any method of desensitization likely to prove successful? If not, can you recommend a substitute for the ordinary cosmetics?

A.—The constituent of face powder most likely to cause dermatitis is orris root. It is commonly used in face powders and has a delicate odour of sweet violets. Another but much less likely possibility is lycopodium; while other constituents are rice starch, arrowroot starch, maize starch, barium sulphate, bismuth salts, chalk, kaolin, kieselguhr, canolin, magnesium carbonate, stearate of zinc, talc, and zinc oxide. The most satisfactory treatment is elimination of the cause; orris-root-free powder is obtainable. Hyposensitization is tedious and should be considered only in exceptional circumstances.

Sunstroke and Heat-stroke

Q.—Why have topees and double-terais been discarded by both the Services and civilians in the Tropics? I met with many cases of both sunstroke and heat-stroke in Mesopotamia in 1916–18; this in spite of head-covering and spine-pads. Playing cricket, golf, or tennis without head-covering obviously reduced the player's stamina. Women in the Services, when they chose, walked about in Ceylon without any kind of hat.

A.—It is now believed that sunstroke really amounts to heat-stroke, and that insolation does not occur merely from the direct impact of the sun's rays upon the unprotected head or nape of neck. This is dangerous only when body cooling proves inadequate. Certainly experience has shown that it is possible to live and work in the Tropics with bare torso and no hat; indeed the incidence of prickly heat over the trunk is probably much lessened. Nevertheless, some may well consider that the pendulum has swung too far, and the present-day habit of undress in the Tropics may be nothing far short of a cult or a fad. Premature exposure of untanned skin to the tropical sun is certainly unwise, especially in those not in first-

class physical condition. In discarding spine-pads and topees an individual may be depriving himself of a certain measure of comfort, as well as a pleasing shade to the eyes against glare. It may be significant that the indigenes in desert countries usually wear clothing to protect both body and head. The effect of sunlight on the naked body is comparable to exposure to a source of radiant heat. Even in the Tropics a stoker in the boiler-room of a ship would hesitate to expose his bare torso to the radiant wild heat emanating from the engines. Although tanning of the skin protects against the painful effects of ultra-violet radiation, the body is rendered more sensitive to heating effects. Such a person absorbs more energy and will be heated more than one with a fair skin. This effect may be sufficient to tip the scales when the thermoregulatory body mechanisms are being strained. The interested reader may be referred to the recent monograph of H. F. Blum, "The Physiological Effects of Sunlight on Man" (*Physiol. Rev.*, 1945, July, 483), and also to D. B. Dill's *Life, Heat and Altitude* (Cambridge, 1938).

Incidentally one should be cautious of accepting the diagnosis of "sunstroke" in this country. Spontaneous subarachnoid haemorrhage from a leaking cerebral aneurysm is not infrequently so labelled.

Narcolepsy

Q.—Is there any effective treatment for a man of 55 who is subject to falling asleep suddenly without warning? It came on after the 1914–18 war, and prevents him from undertaking serious employment.

A.—This patient is evidently suffering from narcolepsy. The only effective treatment is amphetamine sulphate, which may be given in doses of 10 mg. two or three times a day, but the last dose should not be taken later than teatime lest it interfere with sleep at night. Marked hypertension would be a contra-indication.

LETTERS, NOTES, ETC.

Varicose Ulcers and Penicillin

Dr. MARGARET VIVIAN (Bournemouth) writes: One of your correspondents asks (Aug. 3, p. 183) whether penicillin has been successfully used for varicose ulcers, and so my own experience may be of interest. The patient had an ulcer in the middle of a tough scar half-way down the anterior surface of the tibia. The scar was originally due to an injury in the hockey field, and has been the site of varicose ulcers on two previous occasions. This time it started in 1939 with a slight abrasion, which spread rapidly until it was about 5 inches long and 2 inches wide. Various local applications were used without success, and the patient feared that he would carry this painful and indolent ulcer to his grave. In April, 1945, I was able to obtain penicillin cream, and immediately the ulcer became cleaner and began to heal. The only other treatment was the occasional application of lint soaked in a 1% solution of allantoin. The healing process was very very slow, and the final stage seemed interminable, but now, sixteen months after the first application of penicillin, the skin is whole.

Woolner's Tip

Dr. G. D. SUMMERS (Lincoln) writes: May a nephew of Thomas Woolner thank your correspondent for his kindly note (Aug. 3, p. 170)? Osler in his *Principles and Practice of Medicine* (8th Ed.) wrote of tophi under gout: "The student should learn to recognize, on the ear margin, Woolner's tip." Bland-Sutton used to speak similarly. Lovers of art among your readers may be interested to remember that Woolner was Rossetti's model for the angel Gabriel, Christina being the Blessed Virgin Mary, in "The Annunciation" in the National Gallery.

Duodenal Ulceration

Dr. ROSA FORD (London, W.1) writes: May I refer Dr. J. J. Kennedy (July 27, p. 136) to the work of F. A. Pickworth (*Proc. roy. Soc. Med.*, 1928, 21, 972) and P. Watson-Williams (*British Medical Journal*, 1928, 1, 931) on the aetiology of duodenal ulcer? Acting on their theory that infection from a remote septic focus is the cause of the ulcer, I once had the opportunity to treat a case (regarded as hopeless by a physician) by drainage of the nasal sinuses, with prompt and lasting success. A full report was published in the *Clinical Journal* (1945, 74, 190).

Remedies for Herpes

A reader has pointed out that in the answer to a question on the above subject published in the *Journal* of May 25, p. 822, no mention was made of the medical memorandum by E. S. Hawkes on contramine for herpes (*B.M.J.*, Sept. 25, 1943, p. 391).

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 17 1946

THE ETHICS OF CONTRACT MEDICAL PRACTICE

BY

A. G. BADENOCH, M.D.

It is an immemorial custom to return payment for any service rendered. Organized delivery of any service—for example, water-supply by a municipality, or letter-carrying by the Postmaster-General—does not alter this. The traditional method in medicine, notwithstanding ill-informed statements to the contrary about Chinese practice, is that the patient pays the doctor. Where the medical services rendered must of their nature be organized, and even to some extent compulsory, as in infectious disease treated by a local authority, the rule of payment still holds, though here payment is made through the rates. One great advantage of this is that the service is made available even to those who are too poor to pay rates, and may be imposed compulsorily on those who might be careless about disease likely to spread to others. In a similar way the law has power to intervene in the case of children whose parents might neglect their health. There is no such thing as a free medical service; all must be paid for, directly or indirectly.

Broadly speaking, in most health matters the onus is thrown on the individual to seek treatment for his ailments. This is well warranted by tradition and is a very sound attitude towards the matter. Until comparatively recently the individual was rightly regarded as the custodian of his own health. The growth of industrialism, with its highly urbanized and slum-housed population, created a demand for evolution of medical practice in the direction of compulsion. The miserably low wages paid to the workers, their concentration in slums that were both mind- and body-destroying (I make no mention of the soul), their separation in time and place from the healthy life of the countryside where illness and the doctor were untoward events rather than the everyday feature these have become, were factors that led the humanitarian-minded to press for some form of organized medical treatment by contract. On the other side, sickness-rates were rising and employers of labour were constantly faced with a problem of sickness-absenteeism that appealed to their charitable and their business instincts as something that must be remedied. The trend of the times pointed to its being palliated by an Act of Parliament; the result was Lloyd George's scheme of State-controlled medical insurance for wage earners.

Example of the Panel Service

This has now operated for nearly a third of a century, and we are able to assess some of its results. The demand for cheap and readily available doctoring that had given rise to the medical-aid clubs of the industrial centres was universally met all over the country. Doctors, at first somewhat loath, proved themselves fully co-operative. Though handicapped by a low scale of payment (which, indeed, has relatively remained about the level of the old sickness benefit societies), the panel doctors made an honest attempt to grapple with their growing lists of insured persons and, what is more significant, with the growing proportion of patients seeking medical aid. Their competence, industry, and even heroism need no advertisement here, though many sections of the Press have been strangely silent about their labours. It is perhaps relevant to remind readers that the expectation of life of the doctor is easily the lowest among the professions, in spite of his obviously favourable position *vis-à-vis* actual disease.

On the other hand, there is at the moment an outcry that the panel patient is not being fairly dealt with. It is, of course,

a *prima facie* case against any form of contract service that this is so. To say so is not to attack the panel doctor, but rather to rail against that very fundamental element in any craftsmanship that finds the pleasure in the work enhanced by the pay it brings. But we need not thus, with the ignorant, rail at anything or anybody. It would be a very inhuman doctor who did not find some consolation on thinking that the guinea in prospect did offer some small consolation for a broken night's sleep. It would be a very unusual man (and one perhaps culpably indifferent to the needs of his family) who did not attempt to offset the poorly paid drudgery of slum practice by having a number of patients who paid him on a more generous scale than the local insurance committee. Much of the present dissatisfaction, real or inflated, might have been prevented had successive Ministers of Health dealt more generously with the doctors. The public, like every other person or body, cannot expect a good service without paying for it.

An Unalterable Law

To receive due remuneration is honourable in any craft or profession. If the payment is direct, by case treated or by individual visits paid, it does enhance the doctor's pleasure in his day's work. This is incontrovertible, and as a law of human nature it is, I venture to say, unalterable. Only a perverted view of the dignity of service and the remuneration thereof, such as is gaining impetus from the sorry results of over-industrialization, would hope to have it different. This goes outside my title, but I am tempted to offer the solution and finish with this part of the subject: give every man adequate reward for his labour and, with very simple machinery to deal with the hard cases, the doctor will receive his, and receive it directly from his patient without the intermediary of approved society, local authority, or Ministry of Health. Whatever desperate remedies the desperate disease of "slum-dom" requires and may find, this should be kept before the medical profession as an ideal to be achieved at some future date.

Consider now the patient's side of the question. Does anyone wish to be a contract patient, whether of panel or State? The answer is nearly always negative, and the few affirmatives come from those who are so sunk below the poverty level that they know nothing else. I have been in practice for a quarter of a century among all classes, and I have never yet been approached by a patient, rich or poor, in sickness or in health, with the request that he and I should enter upon a private contractual arrangement for my medical services. I draw the conclusion that contract medical practice has been forced on the people by their sub-human circumstances and that they have accepted it only as the lesser of two evils. The free man likes to choose and to pay his own doctor.

One now enters on the delicate ground of the reaction of the individual patient to the medical contract he has, perforce, entered upon. I have been honest about the doctor; he gets an enhanced pleasure out of work that is paid in proportion to the amount of time and trouble he has expended. What about the patient? An equally honest answer may be given without hurting anybody's feelings. Fundamentally, the average patient is slightly ashamed of the business. That is how most people feel when they take the first step to avail themselves of a contract of this kind. They would prefer, as they may often be overheard saying, "to pay their way." Legally wrong, this is very human. From the outset the contract produces a sense of inferiority.

The Patient's Reaction to the Contract

A sense of inferiority is always a bad thing. Like everything that is bad of itself, it produces its results in different

ways according to the individual in and through whom it is operating, but its results are always bad, in varying degree. They are bad when a patient tolerates illness, even, severe illness, as many do, rather than trouble the doctor. They are bad when a patient pays twice over by going to a doctor outside the agreement and paying his fee. This happens much more commonly than some advocates of contract practice care to believe. It has even been provided for in the new Health Service Bill.

There is yet another bad result of this sense of inferiority. It works in a more subtle way than the foregoing, and may not be so immediately apparent as a result of it, any more than the aggressiveness of certain characters is always recognized by their companions as due to an "inferiority complex." It leads to a wrong attitude both to illness and to seeking its alleviation. It is a fruitful cause of lowering the mutual respect that should exist between doctor and patient. Put crudely, it may be clothed in the words: "I am entitled to it and I am going to have it." It is this attitude that leads to the crowding of the doctor's waiting-room and the swamping of his day's list with a horde of trivial minor complaints that absorb the time he would gladly spend on the more serious cases. Inevitably, it leads in the doctor's mind to a new approach to the problem of each individual new case, an approach that has deteriorated from the old sympathetic approach of the family doctor.

I do not mean that this sense of inferiority is the sole cause of that multiplication of minor maladies that we all know so well. But it must rank causatively along with slum conditions, enslavement in bad factories, rubbishy foods, and the absurd attitude to health suggested by advertisements of patent medicines. Most of these minor maladies could be alleviated, cured, or allowed to pass off with the exercise of a little domestic medicine, natural hygiene, and/or patience. And all these factors are increasingly lacking in those whose minds have been debauched by thirty years of industrialized mass-produced "medicine."

It is scarcely possible to over-stress the violence that has been done to the mass of our people by this faulty attitude to what is beginning to get lip service as positive health. It is this, and not any slackness, or incompetence, or unworthy discrimination on the part of the doctors, that is responsible for most of the disrepute into which "panel medicine" is falling. Whether an extension of the system to include 100% of the population is likely, when the system has had time to evolve, to produce improvement and not have the effect of levelling down the practice of medicine to a controlled uniformity is a question that should be answered, so far as it can be answered, from the evidence available from the past, and not according to the wishful thinking of any particular political ideology.

HEARD AT HEADQUARTERS

Good Hearing

Many praises were accorded during the recent A.R.M. to those responsible for the acoustics of the Great Hall. In former days the proceedings were frequently interrupted by complaints from members at the back of the hall that they could not hear what was said, and when the microphone was adjusted differently it might be that those within a yard of the speaker were unable to distinguish one word. These difficulties have now been overcome by a system which enables speakers to be heard with equal clearness at the Press table and in the back gallery. At the recent Representative Meeting there was not one complaint that a speaker was not fully heard.

Building Improvements

Another matter which has been put in hand by the energetic Building Committee under the chairmanship of Mr. A. M. A. Moore is the ventilation of the council chamber. Long meetings take place in that chamber, and as there is a tendency on the part of members of Council to appeal quite early in the day for the relaxation of the rule against smoking the physical atmosphere becomes obscure in inverse ratio, no doubt, to the clarification of the mental atmosphere. A firm of experts, after examining the present method of ventilation, has recommended

the installation of air shafts and ventilators at varying levels, so as to maintain a constant lateral movement of air. No mechanized devices such as noisy fans need to be employed, and there are no maintenance costs once the system has been installed. It is expected that when the new system is put in all the stagnant air and tobacco-smoke will be removed, and the chamber will be kept fresh for twenty-four hours of the day—not that Council meetings last as long as this.

Lighting in the Library

Yet another plan for the improvement of the amenities at B.M.A. House is the projected installation of table lamps in the library, with individual fittings to be controlled by the reader, thus bringing it into line with the best public and private libraries. It is also proposed to have a sectional form of shelf lighting. Fluorescent lighting has been fitted in the staff basement, and it is expected that presently it will be possible to introduce the same lighting into other rooms at present not well illuminated. Another service to members is under consideration. This is the rearrangement of the basement garage to provide free accommodation for members' cars during ordinary office hours and at other times by arrangement, together with a minor repairs service, for which the member will be charged at normal rates. Certain matters have yet to be discussed, however, before this can be brought into operation.

Correspondence

The Bill and the Capitation Fee

SIR,—Dr. S. C. Alcock (*Supplement*, July 27, p. 32) would have us believe that the inadequacy of the N.H.I. capitation fee, now as always, has a simple explanation. For twenty-five years, it would seem, the Insurance Acts Committee has been the acme of ineffectiveness and inefficiency. A curious accretion of timorous souls, its contacts with the Ministry of Health have amounted only to one long, dreary succession of failures. It has achieved nothing and therefore should be replaced by a more competent body.

If such is the case and I interpret Dr. Alcock aright, two questions demand immediate answer. Why has the insurance practitioner been so shockingly served over the years by his representatives on Panel Committees, on whom rests the onus of electing the direct representatives who form the majority of the personnel of the I.A.C.? And what is one to say of the negligence of the various bodies, Panel Conference and Representative Body included, responsible for the election of other members of the Committee?

The suggestion that another body, possibly led by counsel, should act for the profession in dealing with the Ministry is not new. It was turned down heavily when last considered. The I.A.C. is the executive of the Panel Conference, to whom it is responsible and whose policy it seeks to implement so far as lies in its constitution and in its powers. Without the confidence of the Conference it could not function or continue to exist. If at the present time it does enjoy that confidence such statements as "the I.A.C. had failed, as usual, so miserably" are of the greatest disservice to the profession, creating distrust and disharmony. The responsibility for the inadequacy of the capitation fee rests, as it has always rested, with the Ministry. To imply that the I.A.C. shares this responsibility is, in fact, to place the blame squarely on the shoulders of the injured party, the panel practitioner himself, since his chosen representatives have so signally failed to secure for him just payment. Dr. Alcock's indignation at the unjust capitation fee is shared by every panel practitioner, but his assumptions travesty the facts. Unfair criticism does not make for strength and is destructive of all effort for the common weal.

The present Minister has accepted the findings of the majority report of the Spens Committee—an official admission of the inadequacy of the N.H.I. capitation fee. It is perhaps not generally realized that it was largely at the instigation of the I.A.C. that the Spens Committee was set up. The report of a special meeting of the I.A.C. dealing with the latest develop-

nts appears in the *Supplement* immediately above Alcock's letter; it concludes with a resolution for action, passed, after long discussion, unanimously. May I finally draw attention to Dr. Alcock's suggestion that a future service capitation-payment will no doubt be influenced by the present capitation fee. Will it indeed, Sir? Any influence will be to the good if it confirms the profession a realization of the necessity for vigilant scrutiny of all financial terms, and the firm refusal even to consider inadequate remuneration. The time to make the stand is before the contract is signed—if it is to be signed at all.—I am, etc.,

High Wycombe.

D. J. B. WILSON.

The Public and the Bill

SIR,—Friday's *Times* leader, which throws the uncertain light inapt historical comparison unfairly on one aspect of our fight for freedom, again emphasizes the inadequacy of our press. Could we not have for lay consumption a monthly detachable supplement to the *B.M.J.*? Laid on the tables in our sitting-rooms, or even with its holder pages pinned to the walls, this supplement could present facts that the public needs to know and cannot find in the lay press. Surely Mr. Abel's nursery rhymes deserve a wider public. And no doubt he could also supply a comic strip of Basher the Brutal T.B. and the Beastly Band! But this is looking ahead to the days when the "*B.M.J. Monthly Supplement*" might be a popular family magazine giving scope to varied talents. At this stage of our story it is galling to see on the one hand misrepresentationounding and on the other hand truth buried between pages of technical dissertations in the *B.M.J.*—I am, etc.,

South Ruislip.

WILLOUGHBY CLARK.

Protection of Practices

SIR,—Dr. G. A. K. Steen's accusation (*Supplement*, July 20, 1946) leaves me cold. He should not have expected 100% success from a scheme which was obviously one-sided. All credit to those who tried to work it.—I am, etc.,

London, N.9.

M. P. K. MENON.

Medical Unemployment

SIR,—I feel I cannot let the letters from unemployed ex-service doctors published in the *Supplement* the last week or so go unanswered. I and my partner before the war and during the early war years had an assistant, and a practice that took all three of us to cope with it. Then our assistant was called up and for three years or more we struggled on doing not only our own work but that of a local man as an absent practitioner. Now we have been seeking another assistant for over twelve months.

We can offer £700 per annum, the use of a somewhat dilapidated car, and a house to live in, and if we can find a man who fits in with us we are prepared to offer a full third share in the practice. The house has just been rebuilt after being demolished by a bomb, and the garden is a mass of rubble—in an industrial population. We can get no British offers and have to have an alien assistant, who is single and lives out. It seems a queer thing that we who are tired and overworked cannot contact those who are seeking for a place to settle. But this practice means hard work amongst a very good type of artisan and labourer.—I am, etc.,

"PRINCIPAL."

SIR,—I can well sympathize with the opinions of "Unemployed Ex-Serviceman" and Dr. G. L. E. Thomas (*Supplement*, Aug. 3, p. 58), and can confirm all their statements from the light of bitter experience.

I was demobilized in August, 1945, and I am yet unemployed. I have applied for various posts advertised in the pages of the *B.M.J.* and did not receive the courtesy of a reply to one of them. I have come to the conclusion from my observations and experience in civilian life that in the Army you get employment, courtesy, and manners, because, I suppose, there is some authority to enforce the ordinary kindly relations between man and man. That contributed greatly to the winning of the World War II. We ought to try and win the peace by behaving

in a somewhat similar manner. The fact that there are unemployed ex-Service doctors is something that must cause grave anxiety in time to come. The remedy is simple. Ex-Servicemen should be employed as well as having priority over other candidates. I am not speaking on behalf of myself although I was a volunteer in H.M. Forces, but for all who wore the King's uniform at a time of agony and distress.—I am, etc.,

ANOTHER EX-SERVICEMAN.

SIR,—The professed aim of the Labour Government in introducing the National Health Service Bill is to provide better medical services, particularly in the industrial or poorer areas. The standard of medical practice in these areas leaves much to be desired, chiefly because of the paucity of doctors there. Whether the N.H.S. will improve matters remains to be seen. Years will pass before the N.H.S. can alter the present position. An increase in the N.H.I. capitation fee, say to 15s., would enable overworked practitioners to employ partners or assistants and so provide better medical services. That there is already serious unemployment among doctors returned from the Forces is indisputable.

I advertised for an assistant in the *B.M.J.* ("with or without view"), and I have been literally inundated with applications. The great majority were from men (and from women too) whom one would be proud to employ both because of distinguished war record and on account of academic distinction.

It is quite impracticable to answer but a few, much as I should like to thank each and all. If the B.M.A. has the interest of those returned doctors at heart it will push on with securing an adequate capitation fee before it allows itself to compromise with the Government on any other problem. I hope applicants will realize the position and that they, too, will join with the panel doctors, in their own interests, in trying to secure a fair capitation and so alleviate the pressing unemployment.—I am, etc.,

"M.D."

Domestic Help for Doctors' Wives

SIR,—Surely Dr. B. Richardson Billings (*Supplement*, July 20, p. 29) is unduly pessimistic about the future of doctors' wives under the National Service. The doctors have been asked to place their services and their surgeries at the Government's disposal; but no request has yet been made to the doctors' wives either to keep the said surgeries clean, or to attend to bells and phones.

If I am asked to work in the Government scheme, free, gratis, and for nothing, while my M.P. draws £1,000 a year for doing less, the answer will be in the negative.—I am, etc.,

A DOCTOR'S WIFE.

H.M. Forces Appointments

ROYAL NAVY

Surg. Cmdr. A. L. McDonnell has been placed on the Retired List. Acting Surg. Lieut.-Cmdr. G. J. Potts to be Surg. Lieut.-Cmdr. Temp. Surg. Lieut. G. M. Baird has been transferred to the R.N. Permanent List in the rank of Surg. Lieut.

ARMY

Col. J. G. Gill, C.B.E., D.S.O., M.C., late R.A.M.C., has retired on retired pay and has been granted the honorary rank of Major-Gen.

ROYAL ARMY MEDICAL CORPS

Lieut.-Col. R. N. Phease having attained the age for retirement is retained on the Active List supernumerary. Major (War Subs. Lieut.-Col.) D. A. O. Wilson to be Lieut.-Col. Short Service Commission.—War Subs. Capt. H. R. Vincent, from R.A.M.C., Emergency Commission, to be Lieut., and to be Capt.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Major F. R. Fletcher having attained the age limit of liability to recall has ceased to belong to the Reserve of Officers.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major E. White having exceeded the age limit has retired, retaining his rank.

War Subs. Capt. R. D. Guy to be Capt.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Subs. Major (now War Subs. Licut.-Col.) A. J. Watson to be a Consultant Surgeon, and has been granted the local rank of Brig.

To be Licuts.: W. R. M. Alexander, E. L. Dutta, S. A. M. Garibian, J. R. Edge, J. A. C. Edwards, J. F. Edwards, D. M. L. Evans, J. D. Hallissy, C. J. MacD. T. Jones, W. R. Jukes, J. D. Martin, J. M. U. Philip, J. M. Reed, M. McK. Shaw, J. B. Cavanagh, R. O. F. Hardwick, D. J. B. Johnston, A. I. Macleod, P. Pau, R. Schneider, S. Shubsachs, and J. Y. D. Wakcham.

Association Notices

SCOTTISH COMMITTEE

SESSION 1946-47

Election of three representatives by the Group of seven Divisions comprising Orkney, Shetland, Caithness and Sutherland, Inverness, Outer Islands, Ross and Cromarty, and Argyllshire.

In accordance with the Standing Orders of the Scottish Committee nominations for these three vacancies shall be in writing and may be made (a) by a Division, or (b) signed by not less than three members of the Group.

Nomination forms have been sent to the Hon. Secretaries of the Divisions in the Group, and can also be obtained on application to the Scottish Office.

If more than three members are nominated the election shall be by voting papers sent by post from the Scottish Office to each member of every Division in the Group.

Nominations should be sent to me at the Scottish Office, 7, Drumsheugh Gardens, Edinburgh, not later than August 31, 1946.

R. W. CRAIG, Scottish Secretary.

CONSULTANTS AND SPECIALISTS COMMITTEE

Part-time Consultants and Specialists

Notice is hereby given of the formation by the Council of an electoral roll for the election to the Consultants and Specialists Committee of five representatives of members of the Association who are engaged part-time in consultant and specialist practice. Members of the Association who claim to conform to this definition, including those serving with H.M. Forces, are requested to complete and return the appended form to the Secretary, B.M.A. House, Tavistock Square, London, W.C.1, not later than Monday, Sept. 2, 1946.

CHARLES HILL,
Secretary.

Aug. 3, 1946.

BRITISH MEDICAL ASSOCIATION

CONSULTANTS AND SPECIALISTS COMMITTEE

Part-time Consultants and Specialists

FORM OF APPLICATION FOR INCLUSION IN ELECTORAL ROLL

To the Secretary,
British Medical Association,
B.M.A. House, Tavistock Square,
London, W.C.1.

I wish to apply for inclusion in the electoral roll for the election of representatives of part-time consultants and specialists on the Consultants and Specialists Committee. I am a member of the Association and am engaged part-time

in the consultant and specialist practice of.....

Signed.....

Address.....

Date.....

Middlemore Prize

The Middlemore Prize consists of a cheque for £50 and an illuminated certificate, and was founded in 1880 by the late Richard Middlemore, F.R.C.S., of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The Council is prepared to consider the award of the prize in the year 1947 to the author of the best essay on: "The Aetiology and Treatment of Chronic Iridocyclitis." Essays submitted in competition must reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, on or before Dec. 31, 1946. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of no essay being of sufficient merit the prize will not be awarded in 1947.

WEEKLY POSTGRADUATE DIARY

EDINBURGH POSTGRADUATE LECTURES.—At West Medical Theatre, Edinburgh Royal Infirmary, Thurs., 4.30 p.m. Dr. R. M. Murray-Lyon, Aetiology and Diagnosis of Amoebiasis.

APPOINTMENTS

EAST HAM MEMORIAL HOSPITAL.—Honorary appointments. Physicians, A. C. M. Elman, M.D., M.R.C.P., Beryl E. Barsby, M.D., M.R.C.P. Orthopaedic Surgeon, L. Gillis, M.Ch.Orth., F.R.C.S. Ophthalmic Surgeon, I. Spiro, F.R.C.S. Dermatologist, C. C. Ryan, M.D. Assistant Physician, A. M. Stewart-Wallace, M.D., M.R.C.P. Assistant Surgeon, I. E. Zieve, F.R.C.S. Assistant Obstetrician and Gynaecologist, D. G. W. Clyne, F.R.C.S. Ed. Assistant Orthopaedic Surgeon, R. Parkinson, F.R.C.S. Refractor, J. Halperin, M.R.C.S., L.R.C.P., D.O.M.S. Anaesthetists, J. W. Kelsley, M.B., Ch.B., J. Ives, M.B., B.S., D.A., J. A. Lee, M.R.C.S., L.R.C.P., D.A., Mrs. Audrey Marsden, M.B., Ch.B., D.A., Mrs. Ursula Y. Hamilton Paterson, M.R.C.S., L.R.C.P., D.A. Ear, Nose, and Throat Registrar, L. E. Gardiner, M.R.C.S., L.R.C.P., D.L.O. Pathologist, E. H. Koerner, D.M.

RAMSGATE GENERAL HOSPITAL.—Honorary Consulting Urologist, E. Freshman, F.R.C.S. Honorary Consulting Dermatologist, H. A. Treble, M.R.C.P. MACPHERSON, IAN, M.D., M.R.C.P., Honorary Assistant Physician, General Infirmary at Leeds.

SEYMOUR-JONES, J. A., F.R.C.S., D.L.O., Registrar, Portsmouth and Southern Counties Eye and Ear Hospital.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BELLAMY.—On July 15, 1946, at Rankin Memorial Hospitals, Greenock, to Margaret (née Kinloch), wife of Richard Bellamy, M.B., B.Ch. (Licut., R.A.M.C.), of Bridge-of-Weir, Renfrewshire, a son—Peter.

CUST.—On July 21, 1946, at 25, Elvaston Place, S.W.7, to Frankie (née Lyons), wife of Norman Cust, M.D., a daughter—Nonie.

DAYNES.—On August 4, 1946, at Westminster Hospital, to Janifred (née Justham), wife of Dr. Guy Daynes, 48, Greycote Gardens, S.W.1, a son—Jeremy Guy.

GRETTON-WATSON.—On July 26, 1946, in London, to the wife of Dr. B. G. Gretton-Watson, a son.

KITCHING.—On July 30, 1946, at Lorna Lodge Nursing Home, Manchester, to Gwendolene Mary (née King), wife of Dr. E. Howard Kitching, of Belmont, The Avenue, Hale, Cheshire, a son.

PUDDICOMBE.—On August 4, 1946, at Woking, to Doris Marjorie (née Box), wife of Dr. R. T. M. Puddicombe, a son—Robert Eyre.

MARRIAGES

GALLOP—HARRISON OSBORNE.—On July 20, 1946, at Leckhampton, Captain Maurice F. Gallop, R.A.M.C., of Tunbridge Wells, to Nancie (Ann) Harrison Osborne, C.S.P., of Cheltenham.

MACKINNON—SEPTON.—On August 2, 1946, at Walkden, Donald MacKinnon, M.B., B.S.Lond., M.R.C.S., younger son of the late Dr. Ronald MacKinnon and Mrs. MacKinnon, of Oldham, to Kathleen Needham, only daughter of Mr. and Mrs. R. Septon, of Walkden, Lancs.

DEATH

MAYNE.—On August 6, 1946, at Plymouth, Mary Elizabeth, beloved wife of Cyril F. Mayne, F.R.C.S.

RETURN TO PRACTICE

The Central Medical War Committee announces that the following have resumed civilian practice: Mr. Guy Blackburn, F.R.C.S., at 51, Harley Street, W.1 (Langham 3711); Mr. T. Keith Lyle, F.R.C.S., at 42, Charles Street, Berkeley Square, W.1; Mr. G. C. Sawyer, M.S., F.R.C.S., at 6, St. John's Road, Leicester; Dr. J. D. Spillane, at 110, Cathedral Road, Cardiff.

LONDON SATURDAY AUGUST 24 1946

A STUDY OF PEPTIC ULCER

BY

HUGH GAINSBOROUGH, M.D., F.R.C.P.

Physician to St. George's Hospital

AND

ELIOT SLATER, M.D., F.R.C.P., D.P.M.

Medical Officer, Maudsley Hospital

The problem of peptic ulcer has engaged a good deal of attention in recent years because of its high incidence; it has been stated that 10% of all adult males suffer at some time from a peptic ulcer. The disability produced is considerable and accounts for much absenteeism in industry. The degree of disability is evidenced by the willingness with which the majority of patients have come into hospital for a lengthy period of treatment despite the associated financial difficulties.

Many theories have been put forward as to the causation of peptic ulcer, but the occurrence of this condition in man has not been satisfactorily explained. Two theories, however, are attractive: the first that peptic ulcer is due to nutritional deficiency, and the second that psychogenic factors are largely responsible for the disease.

McCarrison (1936) found that the incidence of peptic ulcer was 58 times as great in Southern India as compared with Northern India, corresponding to a very inferior dietary in the former. This was borne out by his experiments with rats fed on the native diets. Other animal experiments, such as those of Slive, Bachrach, and Fogelson (1940), using a modification of the Mann Williamson operation, suggest that a nutritional cause is important. But the degree of undernutrition in Southern India (and in the animal experiments) is not matched in the ulcer population as seen in this country, and, though in our observations it was practically impossible to assess the actual diet of the patients before the occurrence of ulceration, we could not obtain any evidence of gross deficiency.

Psychological Factors in Causation

On the other hand, the play of psychogenic factors alone has seemed unlikely to effect the initial occurrence of peptic ulcer, but nevertheless the role of such factors in the continuance of the condition and in relapses cannot be ignored. General clinical experience provides contradictory evidence: many patients with chronic recurring ulcers appear to be psychologically normal and to suffer no undue stress in their personal, financial, or industrial relations, but yet occasionally the occurrence of emotional reaction is sharply associated with breakdown. One patient, a plumber aged 50, has had five large haemorrhages, each one preceded by a period of great stress. He admitted it was "all his nerves," and he realized that he had an excessive emotional reaction to his difficulties. His sense of justice had led to overwhelming mental upset when he had troubles with his foreman, and he had on other occasions been equally disturbed by financial difficulties and when serious illness overtook his favourite son; in fact he foresaw the actual incidence of his last two haemorrhages. In his reaction to injustice he reminded one of Tom, the subject of Wolff and Wolf's (1943) researches. Tom could show similar emotional reactions, and when upset in this way there were both increase of the vascularity of his stomach mucous membrane and increase of acid secretion. Herein lies a possible mechanism

whereby emotional disturbance could cause exacerbation or relapse in peptic ulcer, given the individual tendency to produce such ulcers. It will be shown from our figures that treatment, though generally effective in healing a peptic ulcer, is followed in a large proportion of cases by rapid relapse in the class of patients observed. While in a few cases relapse is due to lack of co-operation and neglect of instructions given, or to difficulties in carrying them out in particular circumstances, such failure was not evident in the majority. If psychogenic factors are important, then clearly one could hardly expect good results if adequate social and psychological adjustments are not made. In individual cases this is sometimes very obvious, as, for example, in a middle-aged woman with a gastric ulcer who had relapsed twice and in whom a partial gastrectomy was recommended; however, while awaiting admission the ulcer healed rapidly, and in this period she had achieved both personal happiness and a freedom from financial worries which had beset her in her business throughout the war. Further, a young woman with a gastric ulcer near the cardia, which did not heal after two prolonged periods of treatment, achieved rapid healing after she married—though it must be reported that her husband promptly suffered a relapse of his duodenal ulcer.

Other authors have drawn attention to the importance of psychological factors in causing the onset of pain, perforation, or haemorrhage in cases of peptic ulcer. Thus Draper (1942) says that he has frequently observed the onset of these symptoms 1 to 10 days after severe financial loss, a business reverse, a sexual slip, a violent argument, or some personal frustration, adding, however, that very often such episodes were not followed by symptoms. Robinson (1937) attaches great importance to the bodily and mental constitution of ulcer patients, and concludes that "emotional conflict in an individual with ulcer diathesis is alone essential for the production of chronic gastric ulcer." Robinson (1938) believes that the mode of operation of these emotions is through the parasympathetic nervous system. This view is also supported by Necheles (1937), who associates gastro-duodenal hyperaemia with the liberation of acetylcholine by parasympathetic action. In his view "most ulcer patients are persons of the worrying, highly strung type." Further evidence is provided by Davies and Wilson (1937), who examined 205 ulcer patients and 100 cases of hernia, and found a very much higher incidence of psychogenic factors immediately preceding the onset of symptoms in the former than in the latter. Most of these took the form of a change of work, financial difficulties, or illness or misfortune in the family. Wilson (1939) comes to the conclusion that "in recurrent haematemesis and gastro-jejunal ulceration there is reason to believe that psychological treatment certainly offers at least as much hope of saving life as other therapeutic approaches, and, since it is probably directed to the basic disturbance, it may possibly prove more successful in the end." Epidemiological evidence tends to support these views to some degree.

Morris and Titmuss (1944) found a rise in the mortality from peptic ulcer in wartime, which reached its height in the last quarter of 1940, when air raids were severe. Illingworth, Scott, and Jamieson (1944) observed a similar rise in the incidence of perforation at the same time; they do not attribute it to air-raid stress but to the general effects of anxiety and overwork.

The Present Investigation

The original purpose of this investigation was the determination of the part played by psychogenic factors in patients with peptic ulcers. The formation at the Atkinson Morley Emergency Hospital of a small in-patient unit for the treatment of such cases gave us this opportunity. All patients admitted to this unit between February, 1943, and June, 1944, were interviewed (by E. S.). Among them were the present group of ulcer patients, frequently first diagnosed after the psychiatric interview. The patients were then followed up at St. George's Hospital, and it was thereby possible to estimate the results of treatment.

Patients were examined radiologically in the first instance, either at St. George's Hospital or as soon as possible after admission. They were treated, resting in bed, by dietetic methods similar to those used by Hurst; and were maintained on a diet of two-hourly varied feeds with the addition of ascorbic acid, and of sufficient caloric value, so that in fact the great majority of patients steadily gained weight during treatment. Suitable occupational therapy was provided. Healing was observed by repeated opaque-meal examinations at four-weekly intervals, and confirmed in some cases by gastroscopy, and only rarely were the x-ray and gastroscopic findings discordant. The average stay in hospital was 9 weeks. While in hospital the patient's home and working conditions were investigated and discussed with the almoner, and wherever possible advice was given as to necessary readjustments, and contact made with employers, disablement rehabilitation officers, and industrial medical officers. The social difficulties were very much in evidence; most of the patients were men engaged in industrial occupations, many on shift work; travelling time to and from work was considerable; canteen facilities left much to be desired, and wartime restriction of food rendered dieting at home difficult. In addition there was much anxiety because of bombing.

The patients were diagnosed as D.U. or G.U. if radiologically proved or if perforation had occurred, or else as clinical D.U. (C.D.U.) where the symptoms and history suggested this diagnosis, subject to confirmation either by a history of haemorrhage or by a satisfactory reaction to dietetic treatment. No diagnoses of clinical G.U. were made, and it was considered that G.U. was less likely to be missed radiologically; but in view of the analyses of symptoms it is possible that the C.D.U. group contained a few cases of gastric ulcer. Anastomotic and juxta-pyloric ulcers are treated in the discussion as duodenal ulcers, but the former are omitted in the calculation of the relapse rate. Of 72 men radiologically proved to have duodenal ulcer, 7 also presented at the same time a gastric ulcer; and 33 cases of men with gastric ulcer, 3 had also a duodenal

Symptomatology.—Differences in symptomatology were not marked between the D.U. and the G.U. cases. It is usually held that pain in G.U. occurs immediately or soon after a meal, whereas in D.U. it occurs much later. In our series 73% of the male D.U. patients experienced pain more than an hour after food, and all the females had late pain. The remaining D.U. patients had pain that was either early or continuous. In G.U. 82% of male and 75% of female patients had pain occurring late—i.e., over an hour after a meal. Nocturnal pain, also thought to be more characteristic of D.U., was found in 75% of male D.U. patients but also in 30% of male G.U. patients. Test-meal estimations by the alcohol method were done on a number of patients. In 75% of male D.U. patients a figure of HCl greater than 60 ml. N/10 NaOH was reached, whereas in only 30% of male G.U. patients was this figure exceeded. It seems clear that, although peptic ulcer could be diagnosed clinically with a reasonable degree of certainty, there is still a considerable margin of error.

Mode of Psychiatric Inquiry.—All these patients were given a routine psychiatric investigation (by E. S.). At the time of

this investigation it was not known what the final organic diagnosis would be. Standard questions of the type usual in psychiatric consultations were employed, relating to family history, childhood, school and work record, dominant personality traits, marriage and sex life, private worries, and neurotic symptoms. Psychiatric diagnoses were made where possible. Where there were indications for some psychiatric measure of treatment a corresponding suggestion was made. This proved necessary only in three cases. In the whole group of 130 males and 32 females a psychiatric diagnosis was made on 19 males and 10 females, as follows: chronic anxiety neurosis—mild, 5 males; 3 females; fairly severe, 2, 1; mild recent anxiety neurosis, 2, 0; mild hysterical reaction, 2, 0; chronic mild obsessional neurosis, 1, 0; minor mental defect with instability, 2, 1; psychopath—hysterical, 0, 1; paranoid, 1, 0; with ? latent homosexuality, 1, 0; chronic alcoholic, 1, 0; inadequate, 1, 0; compulsive adventurer, 1, 0. At first glance, therefore, we find approximately 15% of psychiatric abnormality, which is not greatly in excess of the 10% which some authorities believe to be the incidence in the general population.

Results

Diagnosis and Sex Incidence.—In the D.U. group there were 72 males and 12 females; in the C.D.U. group, 25 and 8; in the G.U. group, 33 and 12. In this series, therefore, 72% of the ulcers are duodenal and 80% of the patients are male. Although G.U. is relatively rather more common among the women, the difference is not significant. This distribution of the two types of ulcer between the sexes seems to be in accordance with the findings of others. In the mortality figures for England and Wales given by Tidy (1944), however, G.U. outnumbers D.U. for both sexes, and the proportion of males to females is near 2:1 than 4:1 as here. Discussing the statistics of St. Thomas Hospital, Tidy (1945) is inclined to doubt whether the preponderance of duodenal ulcer seen in private practice reflects the state of affairs in the country at large; and under sex incidence he gives for G.U. at all ages 2.6 males to 1 female, and for D.U. 8.4:1. On the other hand, in the 952 patients reported by Jones and Pollak (1945) from the Central Middlesex Hospital the ratio of D.U. to G.U. was 2.3:1; and of males to females was for G.U. 2.4:1, for D.U. 6.9:1. With these findings of ratios, within the limits of error of a small sample, are in substantial agreement.

The relative immunity of the female to peptic ulceration is a point of outstanding interest. Highly suggestive material has been published by Sandweiss *et al.* (1939). In one collection of 70,000 consecutive pregnant women only one active ulcer was found; in another group of 13,780 pregnant women there was no case of ulcer, although there were, for instance, 98 cases of appendicitis and 27 of cholecystitis. Among their collection of ulcer patients, 25 women underwent 52 pregnancies, but on one of them suffered from dyspeptic symptoms during the pregnancy. Collecting published reports of peptic ulcer in children, they found 52 males and 49 females—i.e., there was no comparative immunity of the female at this time of life. They also state that there is a high proportion of endocrine dyscrasias among women with peptic ulcer. The same authors report good results of treatment of ulcer with antuitrin "S".

As will appear from the table of psychiatric findings, our female patients formed a much more neurotic and emotionally unstable group than the males. This seems to suggest that, regarding liability to ulcer a woman must have a constitution altogether inferior to that of a man, and therefore in her case there is some protection afforded by biological and constitutional factors.

Age Distribution.—Taking all patients together, the mean ages (in years) for the males were: All D.U., 39.20 (D.U. 38.97; C.D.U., 39.84); G.U., 46.76. For the females they were: All D.U., 36.25; G.U., 52.75. The standard deviations were (for males): All D.U., 9.86; G.U., 9.50. The distribution of patients according to age was as follows:

Age	No.	Age	No.
Under 20 ..	0	50-54 ..	18
20-24 ..	8	55-59 ..	10
25-29 ..	10	60-64 ..	2
30-34 ..	33	65-69 ..	6
35-39 ..	26	70-74 ..	1
40-44 ..	30	Over 75 ..	1
45-49 ..	17		

from the age distribution it is possible to make a rough estimate of the proportion of the total liability to peptic ulcer which has been survived by a given age, as follows:

Age	Percentage Danger Past	Age	Percentage Danger Past
Under 20	0	50-54	82
20-24	3	55-59	91
25-29	8	60-64	94
30-34	22	65-69	97
35-39	40	70-74	99
40-44	57	Over 75	100
45-49	72		

These figures are of interest in themselves, and are also published because they were used to calculate the incidence of gastric disease in the first-degree relatives of these patients. Although the numbers are very small on which to base such an actuarial calculation, the much larger material published by very Jones yields almost exactly the same figures, as the age distribution in his cases and that in ours were very much the same. Our figures show no significant differences in the mean ages of the various groups (despite the big difference between male and female G.U. groups); but the G.U. patients as a whole are significantly older than the D.U. ones.

Marital State.—Of the male patients 12 were single, 115 married, and 3 widowed; of the female, 17 were single, 10 married, and 5 widowed. The deficiency of married women is very striking and is much too great to be possibly accounted for by chance ($P < 0.001$). This finding clearly fits in very well with the observations of Sandweiss *et al.*, which have been referred to above.

Income Level and Financial Stress.—Considerable importance was attached by Davies and Wilson to financial stress as a cause of peptic ulcer. Precise data on income were collected from 110 male patients in the course of psychiatric history taking. There were no significant differences between the clinical groups, and the mean weekly wage was £5 6s. 9d., with a standard deviation of 37s. One in six of the patients was therefore earning less than £3 9s., which is low. Inquiries on financial stress were made by the almoner, Miss Montgomery, from 87 patients. They were classified into those in whom there was no stress, those in whom there might have been some stress, and those in whom there was obvious stress. No significant differences were found between the diagnostic groups, but stress was significantly more frequent among the women ($P < 0.02$); of those recorded three-quarters had doubtful or certain financial stress, whereas this was true of only one-third of the men.

Family History of Gastro-duodenal Disorder.—In all patients a careful account was taken of ages of parents and sibs and any history of gastric or duodenal disease or indigestion. In many instances the patient was able to report that the relative had had "gastric" disease, for which there had perhaps been several admissions to hospital, with or without operation, and which in some cases had ended in perforation or death; but he might still be unable to say whether the cause was a gastric or duodenal ulcer. These cases were distinguished from those in which there had been a history of indigestion, however prolonged, where the symptoms might have been due to a functional dyspepsia. The former were diagnosed as "gastric disease" and the latter as "indigestion." If to every relative we assign a weight corresponding to the proportion of the risk of peptic ulceration he has outlived, it could be calculated from our data that we had observed the life spans of 126.5 fathers, 134.0 mothers, 127.7 brothers, and 148.7 sisters. The incidence of gastric disease could then be calculated as: in the fathers 9.5%, in the mothers 3.7%, in the brothers 6.3%, and in the sisters 1.3%. It is sometimes suggested that at the present time one out of every ten men can be expected to develop a peptic ulcer in the course of his life; but it is equally agreed that the proportion would not have been nearly so high a generation ago. The incidence of 9.5% gastric disease in the fathers of our patients, then, suggests the existence of a hereditary constitutional factor. It is fair to add that the incidence in the sibs is not so suggestive.

"Gastric disease" shows the same relatively higher incidence in the male sex in the relatives of our patients as in the patients themselves. It is otherwise with indigestion, which the patients frequently referred to as "gastric trouble," in respect of which there were slightly more female relatives affected than males.

Of our 130 male patients 20 had a family history of gastric disease, 19 of indigestion; of the 32 female patients the numbers were 4 and 11. This difference between the sexes is significant ($P < 0.02$). It is probably to be associated with the fact that the females as a group are more neurotic than the males, as will appear later.

Psychiatric Findings

These are given in the accompanying Table. At no point was any significant difference discovered between the male D.U. and C.D.U. groups; these were therefore treated together. At a few points there were significant differences between the groups D.U. and G.U., which will be mentioned as they arise. In all other points the only comparison made will be that between males and females. All differences were tested by χ^2 on the actual numbers observed: where a significant difference between the sexes was found it is indicated by italic type in the Table.

Percentage Incidence of Psychiatric Findings

	Males	Females

Family History.—The incidence of a psychiatrically "positive" family history in all patients together is 25%. This is a much smaller figure than that obtained from neurotic patients, where it is invariably reported as over 50%; and it may be no more than that which would be obtained from a random sample of the population.

Childhood Neurosis.—A history of neurotic traits or of definite neurosis in childhood is much more frequent in the women than in the men ($P < 0.001$); in the men it is not likely to be more frequent than in the general population.

School Career; Intelligence.—The school careers of our patients are probably better than the average; and a purely clinical judgment on examination suggested that they were on the whole of rather superior intelligence. Draper (1942) says that a large majority of ulcer patients have good to superior intellects. Robinson (1937) considers that they are alert and intelligent, but memory and mathematical ability are poor. Factual data in support of these opinions are not given by either author. In point of school record, a significant difference ($P < 0.05$) was found between the D.U. and the G.U. patients, the latter doing less well on the whole.

Occupation and Work Record.—The occupations and work records of the females are not discussed, as they clearly could not be compared with the men. It seems probable that our patients would compare well with the average in occupational level. As reported by Slater (1943), the previous occupations of 2,000 neurotic soldiers were 33% unskilled, 38% semi-skilled, and 10% skilled. In this peptic ulcer group there were fewer in the semi-skilled and nearly twice as many in the skilled occupations. However, the population from which we drew our patients may not correspond with the background of the neurotic soldiers. Work records were classified as poor in those who had had much unemployment or had come down in life from the standards upheld by their parents, good in those who had advanced themselves. There can be no doubt that on the whole our patients were good workers and almost certainly superior to a general average.

Sex Life.—Of the male D.U. patients 27 had led a somewhat undersexed existence; of the G.U. patients, only 3. The difference is significant ($P < 0.05$). Without comparable material from the general population the patients as a whole cannot be regarded as abnormal in this respect. Sex problems and any source of worry in the sex life were found in only one of all the male patients. These findings entirely fail to confirm the contentions of Draper (Draper and Touraine, 1932; Draper, 1942), who believes that, morphologically, male peptic-ulcer patients show a feminine component; he says he has found an "inner sense of insecurity based on actual or supposed physical inferiority, including gynec emphasis," in 84% of them, and stresses worry over a sexual slip as a cause of symptoms. Robinson (1938), on the other hand, regards peptic ulcer patients as being rather more active sexually than the average and "strongly heterosexual."

Past Nervous Symptoms.—Inquiry was made about symptoms of a neurotic kind having been experienced in the past, and about a history of "nervous breakdown"—i.e., a non-organic illness with nervous symptoms involving absence from work of several weeks. Such a history was obtained with highly significant greater frequency from the females ($P < 0.001$). Taking the males alone, the figures cannot be regarded as unduly high.

Personality.—Personality traits are listed under a number of heads. It will be noted that an over-reactive mood and tendencies to anxiety and to a hysterical type of reaction are much more frequent in the females than in the males ($P < 0.01-0.001$). But the preponderant characteristics of the group as a whole, comparing them to what is met with elsewhere in psychiatry, are energetic disposition, and tendencies to anxiety, irritability, obsessiveness, and hypochondriasis. These traits fit in with a well-known psychiatric temperament type, the so-called "obsessional." These findings are in substantial agreement with those of other authors. Draper (1942) states that ulcer patients are conscientious to the extreme, high-principled, and ambitious. Robinson (1937) says they are active, driving, alert, intelligent, restless but easily satisfied, and their activity is ill sustained. The patient is not neurotic in any narrow sense; he is not hypochondriacal or prone to complaining, nor is he either an anxiety or a compensation neurotic. Emotional conflict rages within, protected from the outsider's gaze. There is a strong tendency to worry, and there are no safety-valves for pent-up emotion. Davies and Wilson (1937) describe the ulcer patient as showing more than usual tension; a worker, with an urgent, anxious compulsive quality, a tendency to worry, having an interest in activity and efficiency, liable to develop symptoms with any threat to his security.

From this evidence we believe that the "obsessional" type of personality must be regarded as rather more than normally susceptible to ulcer. But it must not be concluded that all ulcer patients are of this type. The obsessional type of personality is not extremely common, and the majority of ulcer patients do not conform to it.

Bodily Habitus.—In our material the diagnosis of type of bodily habitus was made, only in the males, solely on a visual impression, so cannot be allowed much weight. The impression was gained, however, that on the whole the patients tended to be of the asthenic type. This is in conformity with the findings of Robinson and Brucer (1940), who found that ulcer patients

had significant deficiencies in body weight, chest and abdominal circumference, compared with candidates for life assurance. These differences might, however, be caused by variations in degree of nutrition. In our series the patients at the time of admission to hospital were considerably under their best weight in times of health; the mean loss was for the men 15 lb. (6.8 kg.) and for the women 11 lb. (5 kg.). A general tendency among ulcer patients towards the asthenic or linear type of build is, however, also shown in the skeletal measurements taken by Feigenbaum and Howat (1935), though these authors are themselves sceptical of the interest of their findings.

Neurotic Symptoms.—Obvious neurotic features were not commonly found on examination in our series. A neurotic reaction to the illness was adjudged to be present in 13 patients—9 male and 4 female—and in 41 males and 9 females there was a good deal of hypochondriacal preoccupation. An exploration of psychogenic precipitating factors was conducted on a superficial level, and patients were asked to what external cause they attributed the onset of their symptoms. Most of them could give no reason, but 18 of the men suggested irregular meals, generally due to conditions of work, 9 worry over home and other affairs, 8 having to work in "fumes." The circumstances of their lives were discussed in some detail, and it was eventually concluded that psychogenic causes of worry were present in 10 males and 12 females. The relatively greater incidence in the females is highly significant ($P < 0.001$).

Results of Treatment

For the majority of patients the method of treatment appeared to be satisfactory. Steady healing was observed and a stay in hospital of from 6 to 16 weeks was required before healing was deemed to be complete. In a few cases treatment failed, and, following this, partial gastrectomy was done in 6 men for D.U., 4 men for G.U., and 2 gastroenterostomies were done for pyloric stenosis. A few patients left hospital with unhealed ulcers, which healed later. In calculating the relapse rate, only those cases were included in which the follow-up was satisfactory, and patients were omitted whose stay in hospital had been curtailed for various reasons and who relapsed so quickly that it was reasonably certain that complete healing had not occurred. The following figures were obtained:

Type of Ulcer	Sex	No. of Patients	No. of Patients who Relapsed within		
			6 months	12 months	18 months
D.U.	M	48	15 (31%)	24 (53%)	29 (59%)
	F	10	2 (20%)	4 (40%)	5 (50%)
G.U.	M	26	13 (50%)	15 (58%)	16 (62%)
	F	9	4 (44%)	6 (67%)	6 (67%)

Roughly speaking, well over half the patients had relapsed within a year of discharge from hospital. The numbers of the women are too small for statistical handling, but those of the males can be dealt with as in a life table, and on the number observed during any given month and the number who relapsed in that month a survival rate for that month can be calculated. Probabilities of survival can then be progressively multiplied. Dealt with in this way, the chance of surviving without relapse for 3 months after discharge from hospital is 73%, 6 months 62%, 9 months 55%, 12 months 42%, and 18 months 33%. The greatest risk of relapse occurs in the earlier months; one third of the patients can be expected to relapse within 4 months.

Clinical data were searched for indications of possible cause of the high relapse rate. Dividing the patients into two groups—those who recovered and remained well and those who failed to recover or relapsed—and noting the relative frequency of various clinical findings in these two groups disclosed no significant differences, with one exception. This was true of such medical findings as number of weeks of treatment, timing of pain, relief of pain, occurrence of pain at night, drinking habits, test-meal results, as also of all the psychiatric data. It is of particular interest that none of the psychiatric findings, not even the various indications of anxiety tendencies, had any prognostic meaning. The only item that was significantly associated with relapse rate was smoking. Of the 40 heavy smokers observed 22 recovered and did not relapse; of the 5 men known to be only moderate smokers or non-smokers, only

12 did as well. This is a difference between 55% and 24% and is significant ($P < 0.01$). It can, we think, be understood if it is assumed that heavy smoking is likely to aid in the production of peptic ulcer. Men who smoke heavily then subject their stomachs and duodenums to a special stress, and once this is removed (on the advice of the physician) stand a better chance than those who broke down without it.

Discussion

The largely negative results of the psychiatric investigation have to be compared with the findings and the beliefs of other authors. Draper (1942) attributes great importance to the physical reaction to the fear stimulus. Ulcers reflect a disturbance in the inner rather than the outer world, and the fear and guilt associated with sex are very important. Draper recommends that the ulcer patient should receive plentiful help from the psychiatrist. For that author, in fact, the ulcer patient is a neurotic patient. Fundamentally the same attitude is taken by Wilson. Davies and Wilson (1937) showed that there was an unduly high incidence of minor upsetting events, like change of job, etc., in the few days immediately preceding the onset of symptoms. According to Wilson (1939), the illness of the ulcer patient is precipitated by anxiety, and recovery depends on the underlying anxious state. Robinson (1937), on the other hand, protests against the tendency to regard the ulcer patient as neurotic, but he lays special stress on the importance of everyday worries as a cause of ulcer. Our findings are not in conflict with those either of Davies and Wilson or of Robinson. The psychiatrist received no impression that our patients as a whole were being subjected to anything out of the way in psychological causes of worry, nor that such stress as they did have to meet was dealt with in the patient's mind in an inefficient or neurotic way. It is true that in the course of the stay in hospital or during follow-up treatment individual patients sometimes revealed serious causes of worry about which they had been silent up to that point, even during the psychiatric interview. Psychiatric impressions formed during a single interview are therefore likely to provide an underestimate of the incidence of substantial sources of anxiety. The interpretation favoured by us is that the familiar stresses of everyday life were having a more than normally large effect on the vegetative nervous systems of constitutionally susceptible people. This seems to be the interpretation favoured by Robinson but not by Draper. From it we would not conclude, as Wilson does, that the preferred line of treatment is psychiatric, nor would we say that it is at all necessary that a psychiatrist should be called in to deal with more than a small proportion of these cases. No process of psychological re-education is likely to stop these men over-reacting in the autonomic field, and the ulcer diathesis cannot be easily alterable. On the other hand, it is clearly desirable that attention should be paid to sources of worry in the patient's life, and anything that is possible be done to correct them. In the great majority all that is feasible can be done by the physician or surgeon. If he can take some human interest in his patients, not only as stomachs and duodenums but also as individuals, and in their home affairs and personal problems, no more psychiatric expertness than the dictates of common sense will usually be necessary.

On the constitutional side, attention must be drawn to the pronounced differences between the male and the female patients. Two-thirds of the women (21/32) were considered to show a noteworthy deviation of personality from what is, from experience, regarded as the normal range; of the men, only one-quarter (34/130). Frequencies of family history of indigestion, of neurotic traits in childhood, of past nervous symptoms, of tendencies to over-reactivity of mood, to anxiety and hysteria, were all significantly more frequent in the females. We do not believe that this can be explained by a biased selection in gathering the material. It seems most probable to us that, compared with men, women are relatively protected by their constitution or by their mode of life against the development of peptic ulcer, and that therefore a greater degree of somatic instability is required for its development—an instability that shows itself in other visceral and psychosomatic fields. This hypothesis is in accord with the findings of Sandweiss *et al.* (1939). It is quite possible, as they suggest,

that this line of thought will indicate a method of treatment directed towards the underlying diathesis.

The results of treatment were disappointingly poor, and this may in part be attributed to the stress of wartime conditions—difficulties in feeding, long hours of work, bombing, etc.; but on the basis of previous experience it is doubtful whether these adverse conditions played more than a relatively small part in the results. The efficiency of the treatment as given seems hardly open to question as a method of healing peptic ulcers, because in the majority of cases recovery was achieved even under the conditions existing at the time. In any case, the time of treatment was such that few patients could tolerate an extension. The failure is in the prevention of relapses. The discharged patient probably carried out fairly well his instruction as regards diet and taking antacids, but the readjustment of the patient's work conditions and of his attitude to his social problems could only rarely be dealt with satisfactorily. For many reasons it was difficult to effect a change of occupation, even though the absence of unemployment during the war should have facilitated such changes. Where an individual was highly trained he was often unwilling to try a change of occupation, despite his awareness of the unsuitability of the conditions of work in his present employment. In some cases this was due to the risk of a lower level of earnings. Employers, too, could not always find other work for individuals for whom shift work produced obvious difficulties. On the other hand, a few patients did accept retraining under the Interim Scheme, and the resettlement appeared to be satisfactory. For example, the retraining, say, of a bus driver and his resettlement in a new job with better feeding conditions and no spread-over in hours of work seemed effective. In other cases resettlement in a new job with less responsibility and worry proved helpful. It appears from such cases that all the facilities of the Disabled Persons Act should be used to the full in the treatment.

In the group of women with G.U. it was obvious that the social stresses were of a different order. They were elderly, with an average age of 53, and their home and living conditions could not easily be changed. It has been noted above that in the group of women with peptic ulcer there was a marked scarcity of married women, and it is possible that for women living alone the management of nutritional requirements left much to be desired and the standards of family life were not reached.

The incidence of the disease is so high that the problem of providing hospital in-patient treatment is enormous, and many patients with a disabling degree of pain have difficulty in obtaining admission to hospital. At present the only alternative to medical treatment, including attention to the factors just discussed, would be the greater use of surgical methods. However, even if facilities were available it seems hardly justifiable to apply such a major surgical procedure as partial gastrectomy to more than a relatively small proportion of the cases.

Summary

A group of 130 men and 32 women with peptic ulcers, in addition to the usual clinical investigations, were also investigated psychiatrically and followed up after treatment for periods up to three years.

The ratio of D.U. : G.U. was 2.6 : 1, and the ratio of men to women was for D.U. 6 : 1 and for G.U. 2.75 : 1. This corresponds with the findings of other observers. In our series there was a very small proportion of married women.

The analysis of the family incidence of gastric disease and indigestion suggests the existence of a hereditary constitutional factor.

The preponderant psychological characteristics of the male patients as a group were their energetic disposition and their tendencies to anxiety, irritability, obsessiveness, and hypochondriasis. They tended to correspond with the obsessional personality type.

Actual neurosis was uncommon and the incidence of extraordinary causes of psychological stress was small. The stresses observed were principally those inseparable from an ordinary life 10-day.

The women showed a considerably higher incidence of constitutional instability than the men.

The results of medical treatment were disappointing, and on our figures one-third of the patients can be expected to relapse within four months. The failure was not as regards the healing of the ulcers but in the prevention of relapses after return to work.

consequently more attention should be paid in the follow-up period to the adjustment of work conditions, the use of resettlement facilities under the Disabled Persons Act, and the careful discussion with the patient of his social and psychological problems.

We wish to express our gratitude to Dr. G. R. Mather Cordiner for the radiology, to Dr. James Dow for gastroscopy, and to the almoner, Miss H. Montgomery.

BREAST MILK BANK IN MATERNITY UNITS*

BY

MARTHA DYNISKI-KLEIN, M.D., M.R.C.S., D.C.H.

Physician for Paediatrics, West Middlesex County Hospital, Isleworth

The importance of breast milk feeding in the neonatal period and in early infancy has been convincingly demonstrated by statistical evidence comparing the mortality and the morbidity rate in breast-fed and in bottle-fed infants, and by studies dealing with the influence of nutrition on resistance to infection. Incidence of infection in infancy is estimated to be twice as high in artificially fed babies as in breast-fed ones, and the death rate ten times higher. Consequently, the obstetrician and the paediatrician alike are as interested in the promotion of breast-feeding as in the provision of breast milk for babies who cannot be breast-fed. These babies particularly are endangered by circumstances interfering with breast-feeding—e.g., prematurity, and illness in the mother or child. Artificial feeding involves an additional risk.

Much headway has been made in the establishment of human milk services, and efficient breast milk bureaux have been created in many places. These institutions receive their breast milk supply chiefly from paid donors, living sometimes in widely dispersed areas, and require, therefore, rather elaborate arrangements for the collection, control, and preservation of human milk and the medical and nursing supervision of the donors. They are hampered by the inconstancy of supply, which depends very much on the good will of the donors and a constant and costly propaganda. The problem, therefore, is how to avoid these difficulties and to provide a service easily accessible to any baby in need of breast milk.

Every maternity unit may be regarded as an ideal background for the creation of an efficient breast milk service. A considerable surplus of breast milk will be available if the rate of breast-feeding is kept at the highest possible level. "Breast-milk-mindedness" should be stimulated in the antenatal period and be continued during the lying-in period in the maternity unit. An attempt was made to realize this aim, and the appropriate arrangements and their results are outlined below.

Routine expression of the breasts after each feeding-time has been introduced in our hospital since February, 1944, as a means of reducing the most frequent causes of artificial feeding—i.e., engorgement of the breasts and disorders of lactation in the puerperal period. This has enabled us to collect from the lying-in mothers of the maternity units enough breast milk to maintain a breast milk bank continuously.

The milk bank has been supplied by two maternity units: Unit I (Queen Mary's maternity department), with 65, and

Unit II (maternity extension), with 16 beds. Unit I is reserved for pathological cases listed during the antenatal observation or admitted as emergencies. Unit II admits normal cases only. In 1945 there were 1,984 live births in both units.

Method of Collection of Breast Milk

Expression of the breasts is usually started on the second day after birth, and from that time is regularly performed after each feeding throughout the whole lying-in period. Only healthy mothers are taken as donors for the breast milk bank. Most of them have already undergone a full medical examination during their attendance in the antenatal department and associated diseases have been excluded. The mother's hands are thoroughly cleaned, her breasts washed with soap and water, and sterile covers spread, leaving only the breasts free. Mothers and the attending nurses wear masks. Breast pumps, if used, are sterilized, and the milk is collected in sterile containers.

Expression is carried out by a special baby-nursing staff under the supervision of a senior sister. It is best performed manually, and the mothers are encouraged to acquire the necessary skill themselves. Breast pumps are used in cases of considerable engorgement only, or where manual expression is not well tolerated.

The mothers are informed about the purpose of the procedure, and as a rule readily agree to the expression of the breasts and the use of the expressed milk for the benefit of any other baby in need of it. Thus they learn to appreciate the value of mothers' milk. Payment for the expressed milk is not considered, because the measure primarily benefits the health of the mother and her baby.

The amount of expressed breast milk collected is plotted daily, indicating:

Date	
Number of lactating mothers:	
(a) Up to four days after birth	
(b) Five and more days after birth	
Number of breast-fed infants	
Number of ill infants fed expressed breast milk	
Total amount of collected expressed breast milk	
Amount of expressed breast milk distributed to	
(a) Maternity units	
(b) Sick children's wards	

Preparation and Storing of Breast Milk

The expressed milk is pooled in the milk kitchen, which is devoted entirely to the breast milk service. After pooling, the milk is boiled for 5 to 10 minutes, then quickly cooled and kept in refrigerators (temperature 40° F., or 5.5° C.) until distribution. In general it is not stored for more than 24 hours. Any surplus beyond the demand of the maternity units is at the disposal of the children's departments of the hospital. In addition there is a certain equilibrium between consumption and supply (shown below in Chart I) that makes special provision for longer storage superfluous.

Bacteriological and Chemical Control

Twice weekly the milk is examined for its bacterial content. Samples are taken before and after boiling. No viable bacteria have been found in any of the samples after boiling.

Chemical analysis of the milk is carried out from time to time. Average specimens show:

	Before Boiling	After Boiling
Protein	1.8-2.2 g./100 ml.	1.5-3.0 g./100 ml.
Fat	2.7-4.6 ..	3.0-5.0 ..
Lactose	5.7-6.5 ..	6.2-7.3 ..

Thus the pooled expressed breast milk has a composition which is within the physiological limits of mature milk. The concentration of the breast milk constituents due to boiling depends on the duration it is boiled and the provisions against evaporation. Where concentrated feeding is indicated the process of boiling is accordingly extended.

The content of vitamin C in the examined specimens was: before boiling, 3.9-4.6 mg./100 ml.; after boiling, 3-3.4 mg./100 ml. The vitamin C content of breast milk decreases with the duration of lactation and that of expressed breast milk also with the duration of storing. When the boiling is of short duration the

* An extract was demonstrated at the meeting of the Middlesex County Medical Society on March 12, 1946.

ss of vitamin C is small. Nevertheless, ascorbic acid is administered to premature and sick babies to supply their higher requirements.

Principles of Distribution

1.—Maternity Departments

In general, the breast milk collected and boiled at one feeding-time is used at the next one. The milk is distributed to the following classes of infants:

1. *Premature Babies Until They Acquire Sucking Ability.*—Pare colostrum is made available for the first week. Later on, feeding with concentrated expressed breast milk is started if the baby cannot take the necessary quantity. When breast-feeding cannot be established at all, feeding of expressed breast milk is continued until the baby attains normal minimum weight (i.e., about 7 lb., or 3.2 kg.) Breast-milk feeding is the rule during the stay in the hospital.

2. *Babies During Their Own or Their Mother's Illness.*—The milk of acutely ill mothers is not used, though the danger of infection through the milk is remote, but expression of the breast is continued so as to stimulate lactation. Breast-feeding is restored when the conditions allow. For sick babies the milk is diluted, if necessary, with a 3 to 5% rice gruel, according to their digestive capacity. Full-milk feeding is restored as soon as possible.

3. *Babies Whose Feeds have to be Complemented* (e.g., in cases of hypogalactia and sucking difficulties).—Complementary feeding during the lying-in period is performed with breast milk only. This has proved to be a further stimulus in promoting breast-feeding because the importance of feeding with breast milk is thus continuously demonstrated.

4. *Babies Who Must be Weaned.*—Feeding with cows' milk is not started before the tenth day, and it is done only exceptionally, on indication.

3.—Sick Children's Wards

Breast milk is supplied after each feeding-time and stored at the children's departments in refrigerators until individual distribution. The milk is given to:

1. Babies under 3 months of age, during the acute stage of illness. They are fully or partially fed with expressed breast milk, according to their condition.

2. Premature babies admitted from outside or transferred from the maternity units. In addition, colostrum is made available for his group.

3. Older infants with a special indication—e.g., coeliac disease, severe infections, cows' milk intolerance.

Details of Collection and Distribution

The total amount of expressed breast milk collected from Feb. 22, 1944 (the establishment of the Breast Milk Bank), until April 30, 1946, was 6,147 pints (3,491 litres). Analysis of the figures of collection and distribution within the year 1945 (see Table) reveals various factors influencing the working of a breast milk bank, based on a certain number of donors and covering a wide range of emergencies.

Table showing Analysis of Expressed Breast Milk Collected and Distributed in 1945. (1 pint = 0.568 litre.)

Expressed Breast Milk	Amount (pints)		Number of Children Fed
	In 1945	Daily Average	
Total collected ..	3,446	9.44	674
Used in:			
Maternity units ..	2,129	5.83	577
Children's wards ..	1,241	3.41	97
Unused surplus ..	76	0.20	—

The number of infants fed with expressed breast milk during their stay in the maternity units was 577. All but 17 of them could be returned to the breast before discharge. Thus the efficacy of the applied measures is obvious. The rate of breast-feeding on discharge from the maternity units was 98.1%, of supplementary feeding 1.03%, and of artificial feeding 0.87%.

Examination of Chart I shows that the most striking features are:

1. *The Fluctuation of Supply.*—The amount of expressed breast milk collected weekly fluctuates between 44 and 86 pints (25 and 49 litres). (The daily collected quantities show a similar fluctuation between a minimum of 4 pints—2.3 litres—and a maximum of 17 pints—9.7 litres.) This may be explained by several facts. The number of fully lactating mothers necessarily changes from day to day. Between the third and the fifth day of lactation the surplus of milk available for expression is at its peak and declines naturally with the increasing demand of the sucking infant. The amount of expressed breast milk rapidly increases between the fourth and the sixth day, followed by stabilization at a level which is approximately half the highest amount. The quantity of fed breast milk shows

CHART I.—Showing the weekly fluctuation in supply and in distribution of expressed breast milk during the year 1945.

a steady increase until the tenth day. The curves intersect one another approximately on the fifth day after birth (Chart II). Parity also influences the available amount of breast milk. It is estimated that one in five multiparae produces more breast milk than in her

CHART II.—The relation between breast milk and expressed breast milk in ten mothers taken at random and observed during the first ten days after birth.

first lactation period (Chart III). The skill and the co-operation of the staff concerned with the expression is a further factor influencing the result. The pupil midwives in charge of the pro-

CHART III.—Demonstrating the course of the breast-milk and the expressed-breast-milk curve of a multipara and a primipara.

cedure change in groups fortnightly to three-weekly. Finally the irregularity of supply may be affected by the varying number of ill infants. They are removed from their mothers to the sick babies' wing and the whole amount of milk produced by their mothers is pooled.

2. *The Analogous Course of Consumption and Supply in the Maternity Units.*—The approximate daily requirement of expressed breast milk is known to the staff, and the assumption may be allowed that collection is stimulated by the demand. This relation implies that supply could, in emergencies, still be increased within certain limits. It is one of the principal advantages of this type of Breast Milk Bank with the donors on the spot.

3. *The Longer Peak Period in Some Months.*—The weekly collection of more than 70 pints (39.8 litres) lasted four weeks in August/September and in November/December, compared with only two weeks in other months. No proper explanation could be found for this fact. Seasonal influences may perhaps play their part.

4. *The Continuous Supply to the Sick Children's Wards.*—This depends on the available surplus beyond the needs of the maternity. Although the consumption in the sick children's wards is for short periods that in the maternity units, a continuous supply to both departments is possible, so that practically every day in the hospital in need of expressed breast milk can be fed with it.

The question of the reduced nutritive value of expressed breast milk must not be omitted. This is not the place to discuss the whole problem or to set out the arguments, but it should be emphasized that expressed breast milk remains the nutrition of choice in the neonatal period when breast-feeding cannot be established. Where feeding with expressed breast milk has to be continued for a longer period certain additions may become necessary to promote optimal development. At any rate, feeding with expressed breast milk ranks second to breast-feeding and surpasses any artificial feeding, however well "humanized" it may be.

Conclusion

Every maternity unit is a potential Breast Milk Bank. Simple measures that can be carried out within the daily nursing routine are required to create it: (a) Propagation of breast-feeding during the whole period of medical control

(antenatal period; lying-in period). (b) Avoidance of artificial feeding during the stay in the maternity department. (c) Routine expression of the breasts after each feeding-time; collection and pooling of the expressed milk. (d) Organization of distribution.

The advantages are: simple daily routine in collection and preparation; no special staff or financial measures are needed; the donors are on the spot; medical control is easy; adulteration and contamination of milk are excluded; the supply is continuous and adaptable to the demand and could be extended to out-patients. No ill effect has been noticed.

Breast milk banks in maternity units are a valuable step towards the organization of a comprehensive network of institutions for the supply of breast milk.

Summary

A Breast Milk Bank has been in operation at the West Middlesex County Hospital since Feb. 22, 1944.

The amount of breast milk collected from the lying-in mothers in two maternity units has been sufficient to supply the infants in the maternity units and the sick children's wards.

Until April 30, 1946, 6,147 pints (3,491 litres) of expressed breast milk were collected.

Details of the method of collection, preparation, and storing of the milk, of its bacteriological and chemical control, of the principles of distribution, and of the factors influencing the efficiency of the service are discussed.

An analysis of the figures for the year 1945 is given.

The value of breast milk banks of this type for the promotion of breast-feeding and for the building up of a comprehensive human milk service is emphasized.

My thanks are due to Mr. D. M. Stern, consultant obstetrician for generously giving me all facilities and help in performing the work, and to Dr. W. Broughton-Alecock, senior pathologist, and Dr. A. C. Spence and Mr. S. G. Wiener for carrying out the laboratory control. I am particularly indebted to Sister F. Gilham and the nursing staff working under her supervision. On their untiring co-operation and devotion to the task, disregarding the additional burden involved during difficult wartime conditions, has made the work possible.

PAINFUL-FEET SYNDROME AMONG PRISONERS OF WAR IN THE FAR EAST

BY

J. A. PAGE, M.B., B.Ch.
Surgeon Commander, Royal Navy

This account of a distressing and widespread condition seen among prisoners of war in the Far East, resulting from malnutrition, incorporates extracts from the recorded findings of a group of medical officers who, with me, formed the staff of a hospital for prisoners of war in Kobe, Japan, in 1944-5, and who were familiar with the syndrome and had in vain endeavoured to treat it in the several parts of the Far East which felt the weight of the Japanese advance. It will also try to correlate the condition with other diseases better known and associated with malnutrition, with special stress on deficiency of the more familiar factors of the vitamin B complex.

Within three months of the fall of Hong Kong, and later of Singapore, the Dutch East Indies, and the Philippine Islands, beriberi in its typical wet and dry forms became common. It was difficult to treat satisfactorily owing to the inability to give the requisite diet and to the lack of supplies of thiamine, and will not figure largely in this account. Deficiency of vitamins A and C, as revealed by numerous instances of xerophthalmia and mild scorbutic lesions, will also be excluded, as it is thought that the syndrome under review is not specifically connected with those particular deficiencies.

In each of the countries mentioned a condition developed among the men which was known universally and independently as "painful feet" or "electric feet," and often "hot" or "happy feet," the last-named, aptly suggesting the dancing movements and attitude of the sufferers. The term "nutritional neuritis" was also used in the early stages to give the condition a more scientific appellation.

The skin lesions of pellagra were widespread, and somewhat later in 1942 the serious nervous manifestations of this condition were prevalent; and, again, in 1943 and 1944 chronic debility with oedema and general emaciation due to hypoproteinaemia was responsible for severe morbidity and loss of life.

As the name "painful feet" implies and the synonyms suggest, this condition is ushered in by severe burning and aching of the feet associated with hyperaesthesia, raised skin temperature, and vasomotor changes in the feet, with general body-wasting. The condition was first seen three to five months after the Japanese occupation in the various countries of the Far East where large prison camps were established. The incidence rapidly increased in the next few months, and in general showed a substantial decrease in the end of 1942 and the early part of 1943. So far as can be ascertained only very few new cases made their appearance in Japan among prisoners who had been transported there from the South Pacific zones, though a number of old cases recurred or became aggravated during the first winter.

Incidence and Distribution

I give as a conservative estimate the figure of 2,000 cases personally witnessed among approximately 7,000 prisoners of war in Hong Kong between the months of May and December, 1942. In the Philippine Islands, in one camp, some 2,000 cases were reported among 7,000 men between July and December, 1942. In Bilbid Hospital, Manila, the census showed 300-odd cases among 800 admissions. In Java, 1.5% of a camp of 3,500 complained of this condition between October, 1942, and the following January. It was also reported to have been known in Malaya, but no figures are available.

No cases occurring in women in civilian internment camps have been reported, and no opinion can be given as to the question of sex incidence.

The syndrome occurred, to my knowledge, among British, Americans, Canadians, Australians, Dutch, Indonesians, and Portuguese, and is reported to have been common among Filipinos, but Chinese and Indian internees were segregated from the main camps, so that no authoritative statement can be made regarding the incidence among them. The great majority of cases were seen among men of military age, but a number appeared in older individuals, up to the age of 62.

Aetiology

During the period of internment, as this was the first occasion that I or my colleagues had seen or read of this condition, and as there were no adequate means of studying the cases on scientific lines, no definite cause could be attributed. However, certain observations were made, and the following theories as to the causation were suggested.

Protein Deficiency.—The greater part of the protein contained in the daily ration was derived from rice and green vegetables, and usually amounted to about 35–45 g. The minimal amount of protein needed for normal maintenance and tissue repair is probably 30–40 g. daily, provided that the protein contains appropriate amounts of the essential amino-acids. The proviso is also made that the rest of the diet should contain enough fat and carbohydrate to supply full energy requirements. Polished rice (which contains approximately 8% protein of low biological value), leaf vegetables, infrequent issues of meat or fish, and an occasional small ration of white bread provided the entire diet. The daily ration in Shamshupo Camp, Hong Kong, was: rice, 10–12 oz. (280–340 g.); bread, 5 oz. (140 g.); fish or meat, 2 oz. (56 g.); peanut oil, 1 drachm (3.35 ml.). This gave a total protein intake of approximately 40 to 45 g. on days when meat was provided, and a calorific value of about 1,500. This diet provided for a nine-hour working day of manual labour.

Fat Deficiency.—During this period the total daily fat intake seldom exceeded 10–15 g.

Vitamin Deficiency.—All the elements of the vitamin B complex were deficient, as evidenced in the camp by the enormous prevalence

of beriberi and of riboflavin and nicotinic acid deficiency lesions. Many of the painful-feet cases showed these lesions, yet many did not; again, many cases manifesting advanced riboflavin and nicotinic acid deficiency never developed painful feet. Yet, nevertheless, it was considered that this syndrome may have been due to one or other of the lesser-known or imperfectly "developed" factors.

Factor Contained in Grain.—In one specific instance, in Hong Kong, a group of prisoners of war who were separated from the main group and interned for upwards of three months in the civil gaol, and were fed on rice with a rich admixture of barley, did not develop painful feet; nor, so far as can be determined, was the disease present in the several hundred persons under detention at the time, whereas their comrades in the main camp, fed on a poor grade of plain frequently musty rice, did. Furthermore, out of a group of 14 cases which were transferred to Japan and in consequence changed to a good-quality grain plus barley, 13 cleared up within four to eight weeks. The fourteenth, an advanced case, did not, but continued to suffer from swelling and hyperalgesia of the feet (which were also usually livid and sweating) associated with anaesthesia along the distribution of the lateral cutaneous nerve of the calf and loss of ankle- and knee-jerks. In contrast to this, a colleague described the occurrence of some 40 cases of painful feet among 400 prisoners after their transference from the Dutch East Indies to Japan. It is conceivable that many of these were borderline cases in which the change of climate, and the low diet and exposure on the voyage, may have been the deciding factors in precipitating symptoms.

Toxic Theory.—The possibility that the syndrome is due to some toxic factor in old and musty rice must be borne in mind—a theory which is supported by the fact that such rice was consumed in every camp in which the condition occurred. However, in an officers' camp in Hong Kong, where similar rice was supplied, the condition did not occur; but better canteen facilities obtained at this camp, where tinned beef, fish, etc., could be purchased to augment the diet.

Minerals.—Blood chemical studies in which calcium and phosphorus estimations were made were reported to have been carried out on some cases among prisoners of war in the Philippine Islands, and deficiency of these minerals was ruled out as a possible cause.

To recapitulate, it is apparent that a basic deficiency is unquestionable, but a careful controlled observation is necessary to give a satisfactory solution.

Pathology

Owing to the absence of facilities for histopathological study, nothing was known of the pathology of this condition. Certain well-marked appearances were seen in a number of cases which later came to the operating table for amputation of gangrenous extremities (toes or feet). In these cases the skin and the subcutaneous tissue gave, on incision, the gritty sensation which is experienced on cutting dense fibrous tissue. Where the bones of the toes, for example, were exposed, slow necrosis of the exposed portions took place, otherwise the bone appeared normal.

The common complaint of shooting pains in the feet and lower legs, associated later with absence of deep reflexes, suggested a radiculitis of the posterior nerve roots. This will be considered later in conjunction with the association of the complaint with the nerve lesions in pellagra. It has also been suggested that the signs and symptoms can be explained on the basis of a true peripheral neuritis.

One is tempted to emphasize the vascular changes, and this aspect of the pathology of the condition portrays a similarity to Raynaud's disease affecting the lower limbs particularly, or erythromelalgia. In discussing the condition, Prof. Kinoshita, pathologist to Osaka University, who was intensely interested, admitted that late cases were seen among Japanese soldiers returned from the South Pacific, and that studies he had made indicated that the changes were primarily found in the vascular system. It is not clear if he investigated the possibility of changes in the spinal cord, but he found definite thickening of the vessel walls and narrowing or obliteration of the lumen of the small arterioles of the feet and legs. Any degenerative changes in the peripheral nerves were secondary to impaired nutrition.

Clinical Picture

Early.—The disease is normally ushered in by a progressively severe burning sensation of the soles of the feet, especially at the metatarsal heads, associated with redness, slight swelling,

hyperalgesia, and often sweating of the part. This stage was then followed by shooting pains along the dorsum of the inner border of the foot to the heel. The pains were more severe at night and during rainy weather. Sleep was interfered with and often impossible, the patient restlessly pacing the floor or seeking relief by exposing the feet to the cold or soaking them in cold water, or sitting in the typical squatting posture, massaging the feet for hours on end. The facies became pinched and drawn, and there was associated emaciation resulting from loss of sleep and depleted appetite. The pulse was usually rapid, but occasionally slow at rest, with marked tachycardia on the slightest exertion. In the earliest stages the gait assumed a typical attitude, with a wide base, inversion of the feet, and internal rotation of the leg and slight flexion at the knee-joints. The patient shuffles, and when standing he keeps shifting his position from one foot to the other, usually wincing with pain as each foot touches the ground. There is marked hyper-sensitivity of the soles of the feet. In uncomplicated cases the ankle- and knee-jerks and plantar response are present but usually weak. Those cases with concomitant beriberi neuritis complicated the picture by absent reflexes, painful calves, and a positive Achilles tendon sign and squatting test.

Later.—The signs and symptoms all become more aggravated, and mental changes depicting despondency, loss of memory, and general deterioration are noted. The feet begin to show definite circulatory impairment. They become pale and cold, and turn cyanotic when dependent, the cyanosis usually disappearing on elevating the limb. There is diminished pulsation of posterior tibial vessels. Continued exposure to cold eventually leads to gangrene, the great toe being the first affected; then it slowly spreads, and usually becomes self-limiting at the midtarsal joints. (Most, if not all, of the cases of gangrene were seen in Japan, where the added element of a cold climate was the deciding factor in bringing about the gangrenous change. This also came on very rapidly in the case of a number of men who were exposed to prolonged immersion in the sea when a Japanese ship transporting 1,800 prisoners of war was torpedoed off the China coast in September, 1942.) Healing was very slow in the great majority of cases, as it was in wounds and ulcers of any description, but these cases in particular would continue to heal and then break down in a very disheartening fashion.

Treatment and Prognosis

Treatment consisted of rest in bed, with warmth to the legs and feet, and symptomatic analgesia as required. A well-balanced mixed diet with full vitamin content was aimed at. No drug was found which caused any specific improvement. Basing the treatment on the belief that the underlying aetiology was a vitamin deficiency, various available vitamin preparations were used. These included thiamine, per os, parenterally, and intrathecally in some cases. Nicotinic acid, alpha-beta-gamma tocopherol (in the Philippines), vitamin B complex, brewers' yeast, and vitamins A, C, and D have all been used, with indifferent results. Nitroglycerin and histamine were used in an attempt to produce peripheral vasodilatation, with vocal results. Quinine is stated to have given symptomatic relief in some cases. Presacral sympathectomy was performed in five advanced cases by Japanese surgeons with no benefit whatever, and with fatal results in two.

The prognosis is good if the full diet as recommended can be provided. In the later cases, with gangrene, general improvement may be expected with an adequate diet; and under good nursing conditions and adequate diet the gangrenous stumps show a tendency to heal much more rapidly.

Discussion

This syndrome, since its first appearance in 1942, has given rise to energetic discussion among medical men who have had occasion to see and treat it. When the earlier cases appeared they occurred in hundreds, and the matter became of the greatest urgency. The camps were already rife with amoebic and bacillary dysentery. In Shamshuipo camp diphtheria was accounting for upwards of three to four deaths daily. True beriberi was widespread, and pellagra in one or all of its clinical forms was responsible for a huge morbidity. The painful-feet syndrome was usually complicated by one or

more of these conditions. When in the later months of 1942 its incidence was at its height, and in many cases was complicated by beriberi and by the nerve lesions of pellagra, it appeared to be a concomitant symptom of pellagra. The typical advanced case of this condition gave the following history and showed the following nervous changes.

Several months of painful feet; usually stomatitis; glossitis, in most cases preceded by serotol dermatitis, tachycardia of about 140 a minute; severe wasting; diarrhoea at intervals; numbness of a mask-like area of the face around the cheeks and lips, often described as being like a "dentist's injection." Within a few days are experienced numbness of the lower chest wall and upper abdomen, and a feeling of constriction encircling the chest below the nipples and of the upper abdomen. Later, numbness extends to the thighs and legs, with weakness of the leg muscles, loss of sense of touch, and heat and pain in the legs and scattered areas of the abdomen and lower chest wall. Deep touch sense is present. All deep reflexes, cremasteric and abdominal reflexes are absent, and there is loss of the normal flexor plantar response. A well-developed extensor response was seen in some very few cases. In some instances tingling sensations of the fingers and numbness and weakness of the forearms and hands were complained of.

It might be timely here to mention that it was possible in the camp in question to transfer only a very few patients at very infrequent intervals to a hospital on Hong Kong Island where better nursing facilities and food were available. A few of these cases thus survived. Also, this period was marked by the providential arrival of Red Cross parcels and bulk foods so that tinned beef, butter, cheese, cocoa, and ghi were available. A small daily issue of a yeast-flour suspension was also made. This latter had been provided for some months, but the small quantity available and the doubtful efficacy of flour as a medium for the yeast culture rendered its value open to question. This diet, and the arrival of Japanese preparation of nicotinic acid "pellagrin," marked the turning-point in what truly was a nightmare, and many patients began to show gradual improvement. Others who were not so fortunate as to derive the benefits of care in hospital before the arrival of the food became rapidly emaciated, and death followed from right-heart failure. I was transported to Japan at this time—January, 1943—and am unable to give any account of the follow-up of these cases.

In November, 1942, a series of these advanced cases were demonstrated to a number of medical men to show their great similarity to subacute combined degeneration. Some exhibited the posterior-column changes weeks before the pyramidal tract involvement became evident, and vice versa.

It might be suggested that the "painful-feet" symptom is a radiculitis of the posterior nerve roots, the disease affecting the pain-sensibility fibres in the posterior roots and the pain being referred to the skin, muscle, and bones of the extremities. It would appear that the pellagrinous process would concentrate on these structures, in many cases without spreading to or affecting the posterior columns. When the columns become involved and degeneration starts the pain and hyperalgesia disappear.

The absence of an extensor plantar response in the great majority of instances when other evidences of pyramidal damage were present was perhaps due to a concomitant early peripheral neuritis affecting the legs in those cases which had shown the painful-feet syndrome.

Summary

The widespread occurrence of a distressing and serious syndrome among prisoners of war in the Far East, affecting the feet, with accompanying constitutional signs and known as the "painful-feet" syndrome, is described. Owing to the lack of laboratory facilities, diagnostic aids, and controlled investigation, no satisfactory conclusions were reached as to the exact aetiology, but, from the study of a very large number of cases from the onset, the syndrome would appear to be the result of a deficiency of a factor or factors in the vitamin B complex closely allied to the P.P. factor, but primarily affecting the peripheral arteries of the lower extremities, or possibly be due to a toxic factor in old musty polished rice, associated with a low protein intake and reduced vitality.

The appearances in the early stages, when redness and swelling of the feet were the predominant signs, are similar to those of erythromelalgia as first described by Weir Mitchell. It clearly is not an angiocarcinosis and is not associated with a neuropathic diathesis.

The disease is amenable to treatment by replacement of the deficient elements in the diet, but otherwise is rapidly progressive, ending in death or serious crippling deformities.

FACIAL PALSY ACCOMPANYING ACUTE MASTOIDITIS

WITH COMMENTS ON CHEMOTHERAPY IN
ACUTE SUPPURATIVE OTITIS MEDIA

BY

KENNETH R. OGILVIE, M.B., B.S.

Registrar, Royal National Throat, Nose and Ear Hospital, London

Pre-operative facial palsy occurs in about 2% of all cases of otitis media, acute and chronic, but is a much more common complication of chronic or acute-on-chronic otitis media than of acute otitis media *ab initio* (Kettel¹). Presumably, therefore, his complication of acute mastoiditis is comparatively rare. Apart from the four cases now presented, I have only once previously seen a similar case of facial palsy resulting from acute mastoiditis, but have met with the condition three times following an exacerbation of chronic otitis media.

Reports of Four Cases

Case 1.—This patient was a girl aged 5½ years. On Sept. 12, 1945, she complained of headache, but had had no previous ear trouble. On Sept. 14 epistaxis occurred, and on the 15th there was slight left otorrhoea. Next day a pulsating left aural discharge, a tender mastoid process, a partial left orbicularis palsy, and complete paralysis of the lower left face were recorded. Cortical mastoidectomy on Sept. 16 revealed a grossly infected cellular mastoid containing much pus; the sigmoid sinus and dura were both exposed and found healthy. The wound was closed with dependent tube drainage. On Sept. 25 the facial palsy was resolving, and by Oct. 6 recovery was complete. The tympanic membrane and the hearing were then normal.

Case 2.—A boy aged 19 months, when admitted on Sept. 12, 1945, had had left otorrhoea for three days. No history of earache was at this time reported by the parent, whose intelligence, however, was below the average. The left tympanic membrane was thick and red, with anterior perforation. Otorrhoea was profuse, and there was complete left facial palsy (of three days' duration). Cortical mastoidectomy revealed an extensively diseased mastoid containing much muco-pus. On Oct. 17 left facial palsy was still present, but with slight furrowing of the left brow on crying. The tympanic membrane and the operation wound healed. A further follow-up was unsuccessful in spite of several requests to attend as an out-patient.

Case 3.—A boy aged 9 years, admitted Oct. 6, 1945, had had left otorrhoea for two weeks, and left complete facial palsy for one week. There was no history of previous ear trouble. Left cortical mastoidectomy revealed a very necrotic mastoid. The wound was closed with tube drainage, but was reopened on Oct. 27 because of the onset of a low but swinging temperature due to some pocketing of pus. On Dec. 21 the palsy was beginning to recover and the tympanic membrane and the operation wound had healed. Hearing normal. By Jan. 11, 1946, recovery from the facial palsy was complete.

Case 4.—Mr. A., aged 36, attended hospital on Nov. 5, 1945, for left acute suppurative otitis media with otorrhoea. He was treated with a sulphonamide—2 g. daily for five days. The otorrhoea ceased, but some deafness persisted. There had been no previous ear trouble. On Dec. 24 left otalgia followed coryza, and next day there was left otorrhoea. On the 26th the "left side of the face went stiff." Examination on Dec. 28 revealed muco-pus in the left meatus. Deafness was marked, but he had no mastoid tenderness. The temperature was normal. There was complete left facial palsy. Pus was present in both sides of the nose. Cortical mastoidectomy on Dec. 29 revealed a grossly infected cellular mastoid (thick cortical bone) with a deep abscess cavity in the tip containing about a teaspoonful of thick pus under pressure. In the antral region the lining membrane was markedly swollen. A bipp pack was inserted and the upper part of the wound sutured. On Jan. 1, 1946, progress was satisfactory, but the facial palsy was still complete. By Jan. 5 the palsy was beginning to recover in the brow and orbicularis region, and on the 8th recovery was almost complete. On Jan. 22 the patient had quite recovered from the facial palsy, the tympanic membrane was normal, the operation wound had healed, and hearing was normal.

Comment

Faradism was not employed in any of these cases, chiefly because its repetition ruins the morale of children, however painstakingly given, and its value seems doubtful in this type of case. Case 3 showed perfect recovery after nearly eleven weeks of complete paralysis. Splints of any kind were dispensed with for reasons similar to those given above.

Case 4 illustrates one of the pitfalls of sulphonamide therapy in otitis media; there are many others, which are easily

explained by the usual pathological and anatomical changes resulting from the bacteriostatic action of the sulphonamide, which, while localizing the infection of a sensitive and accessible organism, in some cases leaves a focus of living though temporarily attenuated bacteria, while in others a focus of devitalized tissue, incapable of offering any effective barrier to a new infection, remains.

That the latter condition obtained in Case 4 is obvious. His course of a sulphonamide actually or apparently cured the otitis media by Nov. 10; but another attack on Dec. 24 led to an advanced mastoid infection, with a large tip abscess and a facial palsy, within five days, as found at operation on Dec. 29. This infection travelled rapidly by preformed pathways—i.e., those laid down five or six weeks previously.

The position of sulphonamide therapy in otitis media is difficult to assess,² and, as in other forms of treatment, the decision to use or not to use it in any individual case rests as a rule with the general practitioner. He will have to make this decision himself, and, if he decides to administer a sulphonamide drug, then it is as well to bear in mind the possibility that a subsequent relapse or reinfection may with considerable rapidity lead to dangerous complications—perhaps more serious than a facial palsy.

In these cases the infection may be compared with that of a mechanized army advancing over suitable country with supply dumps in abundance already laid down and perhaps a few useful hardened veterans (the sulphonamide-fast bacteria), who have survived the previous rout and have since been lying low, to assist it.

Probably it will prove wiser to reserve chemotherapy for cases which show a tendency to spread outside the mastoid process or which are part of a general septicaemia from some other focus; such cases are best treated in hospital, where all necessary investigations can be made and penicillin be conveniently given, with appropriate surgical intervention if necessary.

Summary

Four cases of spontaneous facial palsy occurring as a result of acute mastoiditis are described; three showed complete recovery at varying intervals after the Schwartz operation; the fourth could not be followed up.

The position of sulphonamide treatment in cases of acute suppurative otitis media and acute mastoiditis is discussed.

I am much indebted to Mr. J. W. MacLaggan, Mr. F. Watkyn-Thomas, and Mr. A. Ryland—under whose care Cases 1 and 3, 2 and 4, respectively, were admitted—for giving me the opportunity of operating upon and subsequently looking after these interesting cases.

TREATMENT OF PEDICULOSIS CAPITIS WITH D.D.T. EMULSION

BY

A. D. FRAZER, M.D., D.P.H.

Investigators of its toxicity agree generally that D.D.T. is practically safe when applied externally as a dried powder or in dilute solution (see *Journal*, 1945, 2, 260). Repeated contact with concentrated solutions is dangerous, but early warning of intoxication is to be expected in anorexia. Scobbie (1945) found that in the treatment of pediculosis capitis the nearest approach to an ideal was D.D.T. emulsion, which killed the lice and persisted in the hair long enough to kill all the larvae. She did not find any toxic reaction or irritation of the scalp or skin after its use. In spite of a fairly large number of publications agreeing generally with the above findings, there still seems to be a fear of possible danger in the use of D.D.T. for pediculosis, and in consequence it is not widely favoured. The experiences of a Nottingham clinic may be of interest, therefore, as during the last eighteen months over 400 patients have been treated without ill effect. At first a 4% solution of D.D.T. in liquid paraffin was used, but since March, 1945, the emulsion found so successful by Scobbie has

been substituted. The formula* is as follows: D.D.T. 2%, naphtha 15%, emulsifying agent 5%, water 78%.

Method of Treatment

Before treatment is started the female patients are advised to bring a scarf or square of material in which to tie up the hair. The emulsion is a clear, colourless fluid, but after application the hair becomes lank. The turban hides this and permits the patient to go home without embarrassment.

A jaconet cape is spread over the shoulders to protect the clothes, and the emulsion is thoroughly worked into the hair and scalp with a two-inch (5-cm.) paint-brush. The patient is then free to go home, and is directed to wash the hair before attending the following day. At this visit nits are removed with a nit-comb. Usually one combing is sufficient, but if the hair is heavily infested two or more may be needed.

At first, observation was maintained for three weeks before the patient was discharged as cured, but with experience of 100% success this period was gradually decreased, until now attendance is excused as soon as all the nits appear to have been removed by the comb—i.e., usually on the second visit. As the majority of patients are sent from antenatal clinics, factory ambulance rooms, and schools, observation is maintained elsewhere, and the fact that these patients are not referred back upholds my belief that cure is indeed obtained.

Observers have found that contact with the emulsion kills lice in about half an hour, and this was confirmed by personal test. Lately, therefore, the hair has been washed one hour after treatment and the usual combing carried out then. So far as one can judge from a small series, this speedy method appears to be as successful as the longer one.

No signs of intolerance have been found, except that in one case, where the woman had extensive impetigo as well as pediculosis, the nose, forehead, and eyelids were inflamed and swollen the next day. This reaction disappeared in a few days.

When the scalp is secondarily infected, the pediculi are attacked first. Treatment is given as described above. On the second day, when no live lice are present, the hair is cut as required and the septic area attended to. This makes the task of dealing with such cases much less unpleasant for the nursing staff and reduces to a minimum their chance of picking up pediculi from the patients.

Summary

Treatment of pediculosis capitis by means of an emulsion of D.D.T. is described. Success is claimed for over 400 patients. No intolerance was experienced in the uncomplicated cases. One patient with secondary impetigo had a brief inflammatory reaction.

The method of treatment is rapid and easy. Washing of the hair before treatment is unnecessary, this saving contamination of towels. From the point of view of the nursing staff the method is the least unpleasant of all previously tried.

I wish to thank the nursing staff, and especially the sister in charge, for their interest and co-operation in this work.

Scobbie, Elizabeth B. S. (1945). *British Medical Journal*, 1, 409.

* Kindly supplied by the makers as "liquid derbae."

The first number of the *British Medical Students' Journal* has recently been published under the editorship of Mr. P. D. Wall. It is designed to appeal to medical students throughout the British Isles, to present them with articles of topical, social, and scientific interest, and to foster international co-operation. The present number differs from the form planned for its successors in being devoted to an account of the World Students' Congress at Prague in November, 1945, and contains an interesting summary of the medical situation in Czechoslovakia as it existed during the winter 1945-6. The shortage of fuel, food, clothing, etc., was severe, the normal food ration for nurses, for example, being equivalent to 1,600 calories a day; and many drugs were unobtainable, particularly those developed in the Western countries since 1939. An interesting comment on housing is provided by the following note: "Houses—25,000 destroyed in E. Slovakia alone. Homeless—200,000 homeless. All but 20,000 housed by November. The remainder housed by the end of November." The next issue of the *B.M.S.J.* is promised for the beginning of October. The price is sixpence to members of the B.M.S.A. and allied organizations, one shilling to non-members.

Medical Memoranda

Criterion for Conservation of the Bowel in Strangulation

Most standard surgical works give sundry criteria of viability of a strangulated portion of bowel, tacitly assuming that if these are satisfied the bowel should be conserved.

CASE HISTORY

A woman aged 51 years, who had had a hysterectomy for fibroid, a year previously, was operated upon by me on Oct. 19, 1945, for strangulation due to a band. The acute symptoms were of 48 hours' duration. A single band was found, strangulating a loop of lower ileum; there were no other adhesions. The loop was freed and, after rather prolonged efforts at revival, pronounced viable, and returned to the abdomen. Convalescence was uneventful, and the patient went home 16 days after the operation.

I was asked to see her again on Nov. 16—i.e., exactly four weeks after the operation. She had the same train of symptoms as before, of 12 hours' duration, but on this occasion a fixed mass was palpable in the lower abdomen. At laparotomy the mass proved to be composed of the coils of a loop of lower ileum all closely matted together and quite inseparable. There were no adhesions elsewhere in the abdomen. A short-circuiting lateral anastomosis was performed, there being just enough ileum below the affected loop to allow of this. The patient again made an uninterrupted recovery, and went home 15 days after the operation. She has remained well since.

COMMENT

There can be little doubt that the matted coils found at the second laparotomy were those of the loop that had been strangulated and conserved on the first occasion. Equally certainly the loop cannot have been fit to be returned, and it may be pertinent to remark that many surgeons would not have done so. It is undeniable, however, that the loop was viable, since it was found, living, a month later.

Two possibilities suggest themselves: (i) That there was a localized non-viable portion that did actually perforate, the perforation subsequently becoming sealed. Against this are the facts that convalescence was uninterrupted and that the adhesions found later were very strictly localized. (ii) The matting was due to organization of exudate from a very seriously damaged but still viable portion of bowel.

Any peculiar liability of the patient to form adhesions may be excluded, since there were none elsewhere.

Two points of interest emerge: (a) In assessing the fitness or otherwise for conservation of a strangulated loop a higher standard than mere viability must be adopted. The bowel must be capable of recovering without such outpouring of exudate as may lead to adhesion formation. (b) Adhesions strong enough to cause obstruction were formed in 28 days exactly. Though this is not very remarkable, such observations are always useful, since precise information as to such time intervals is often required in medico-legal cases, and is rarely forthcoming.

Surgeon, Salisbury General Infirmary.

Spinal Analgesia in an Infant 11 Days Old

The following case may be thought interesting enough to put on record.

CASE REPORT

An infant 10 days old was admitted to the Fleming Memorial Hospital for Sick Children, Newcastle-upon-Tyne, on May 8, 1946, with pneumonia. It apparently also had a patent ductus arteriosus. On the next day abdominal distension developed, and a mass being palpated in the right hypochondrium, a diagnosis of intussusception was made, and an operation was decided upon.

Spinal analgesia appeared to be the method of choice in such a case. The patient was placed on his side on the operating table, which was inclined 15° head up, the child's head being depressed on to his left shoulder. Spinal puncture was performed between L4 and 5 with a gauge 17 hypodermic needle, and 0.5 ml. of "light" nupercaine (1 in 1,500) was injected fairly rapidly without barbotage. The needle was withdrawn and the patient turned on his back, the head-up inclination of the table being maintained for a further 2 minutes, when it was levelled. No vasopressor was used. After 10 minutes analgesia was only just suprapubic, and a further puncture was made. The technique was the same as before, save that a fine Pitkin spinal needle (22 G) was used, as the sharp hypodermic needle made the transfixion of the theca difficult to be perceived, and its narrow bore impeded the flow of C.S.F. The second dose of "light" nupercaine was 1 ml. Analgesia appeared immediately, and extended above the costal margin. Laparotomy

is performed, the analgesia proving adequate, and the infant showing only slight resentment when the subphrenic region was explored. Unfortunately, the condition was not found to be amenable to surgery. There was a congenital atresia of the colon: the mass which had been palpated in the right hypochondrium proved to be greatly enlarged liver. (It must be remembered that the abdomen is greatly distended and examination had been difficult.) Half an hour after operation the patient was remarkably well, and the general post-anaesthetic condition was most satisfactory. Unfortunately, death ensued 24 hours later; necropsy revealed: (1) consolidation of the bases of both lungs; (2) a greatly enlarged liver containing a number of pyaemic abscesses (the result of an umbilical infection); and (3) partial atresia of the large bowel throughout its whole length, with intestinal obstruction.

COMMENT

Although this infant died, the case was, from an anaesthetic point of view, completely satisfactory, and the anaesthetic, far from contributing to the cause of death, permitted an abdominal operation to be performed without any apparent change in the child's condition. The chief interest lies in the dosage employed. The records of spinal analgesia in infants are scant;undy (1942) advises 1 mg. of procaine per pound of body weight, but such a method of assessing dosage is open to obvious criticism. If analgesia be desired to extend up to the fourth thoracic segment, in order to block the splanchnic nerves, as is usually recommended for upper-abdominal operations, it would seem that, with the technique described above, 1.3 ml. would be a suitable dose for an infant of the age of a fortnight or less.

Vesical Calculus complicating Procidentia

As I understand that vesical calculus is rare in women, this report of a case, discovered in a patient of 84 nine months after an operation for prolapse, may be of interest. I have seen only one other case, which was caused by two silk sutures which had been passed into the bladder at a vaginal hysterectomy one elsewhere. I have come across a reference to one in an older patient (aged 93), and treated more correctly by incision of the bladder through the vagina, and Prof. Chassar Moir (1942) recently recorded a similar instance. I also remember Mr. O'Sullivan showing a patient at the Royal Society of Medicine with procidentia complicated, I believe, by 13 calculi. The correct treatment is presumably to remove the stone from below. The fault in the following case lay in not suspecting it. The moral is to x-ray the bladder in long-standing cases prior to operation.

RECORD OF CASE

Mrs. X. had since the age of 28 complained of prolapse. Her trouble was of 55 years' standing, for she was 83 when I first saw her. For a year the prolapse had been complete, and as it was no longer controllable by pessaries she sought surgical relief. She had at some disturbance of micturition for a year; it seemed to be retention with overflow. Her blood pressure was 190/130, but she was pronounced by Dr. Norman Hill to be "as fit as anyone of 83 could be."

On Oct. 1, 1942, I performed a Le Fort's operation on her, pentothal, gas, and oxygen being given by Dr. Langton Hewer. Four days later she developed a urinary infection, which failed to respond to citrates but which was ameliorated in fourteen days with calcium mandelate. She was up in three weeks, and after another month, during which time she had several mild colds and an attack of rheumatism in the left ankle, she left hospital. The *B. coli* was still present in the urine.

Nine months later her doctor wrote to say that for some time he had had haematuria and strangury, and to ask me to take her again. She was admitted in August, 1943, attributing the inconvenience to having caught a cold on her way home. Though now in her condition was as good as previously; the anatomical result of the operation was satisfactory. On Aug. 12 Dr. Organe gave her gas-and-oxygen, and by the cystoscope I at once located the stone. I thereupon did a suprapubic cystotomy and removed a calculus weighing 1½ oz. (49.6 g.), and measuring 2½ × 1½ × 1½ in. (6.7 × 4.1 × 3.1 cm.). The suprapubic catheter was out in fourteen days, and she left hospital after eight weeks. In February of this year she was reported to be very well and free from symptoms, passing urine normally. X-ray examination of the stone shows well laminated composition. There is no foreign-body core, and I presume it to have been formed by long-standing partial retention of urine.

Reviews

FUNDAMENTAL PROBLEMS OF THE ORGANISM

The Directiveness of Organic Activities. By E. S. Russell, D.Sc., F.L.S. (Pp. 196; illustrated. 8s. 6d.) Cambridge: The University Press.

When vitalism passed out of fashion, biology became completely mechanistic. Dr. E. S. Russell is not at all surprised at this, because man, having won his great triumphs through machinery, has a natural tendency to adopt a mechanical explanation. It suits his mental outlook, for he is *Homo faber* (his behaviour gives him no right to be termed *Homo sapiens*). It is only natural that the study of structure became the first aim of biology. In this way a solid body of information was built up, but the field naturalist was at a discount. Indeed, MacBride went so far as to call T. H. Huxley a "necrologist" rather than a biologist. By the turn of the century the inadequacy of this approach was recognized and function has been intensively studied. Even here, too, everything had to be fitted in with the rigid physico-chemical laws known at the time. A good many biologists found this procrustean bed very uncomfortable. Moreover, that all the adaptations of life could be explained as due to the piling up of a vast series of chance variations seemed to them to present a cosmogony as unacceptable as that of the book of Genesis. Free lances like Samuel Butler might talk of "unconscious memory" but for a professional biologist to express belief in the inheritance of acquired characters is to court ostracism.

Dr. Russell provides us with a partial escape from the dilemma. He points out that the mechanistic explanation leaves out of account all that is distinctive of life—the directiveness, orderliness, and creativeness of organic activities—and completely disregards its psychological aspect. Rejecting both the mechanistic and vitalistic hypotheses as equally inadequate, he tackles the fundamental problems presented by the organism as a living and developing whole, striving to complete its life cycle. He illustrates his thesis by a number of fascinating examples of the way in which the organism adapts itself to changes in environment. As Cannon wrote—"the wonder increases when we realize that the [organic] structure itself is not permanent but has been continuously broken down by the wear and tear of action and as continuously built up again by processes of repair." The unstable and self-regulating organization reached in the development of the living organism is, therefore, something totally different from a stable equilibrium which is the natural end state of an inorganic system. "Life is a dangerous adventure; inorganic processes tend towards stability."

This in barest outline is the author's view; he is aware that it is likely to arouse strong differences of opinion, but all must agree on the exceptional interest of the book and on the excellence of the examples chosen to illustrate his contention.

CARDIOVASCULAR DISEASE

Cardiovascular Disease in General Practice. By Terence East, D.M., F.R.C.P. Second edition. General Practice Series. (Pp. 193; 40 illustrations. 12s. 6d.) London: H. K. Lewis and Co. 1946.

This second edition of Dr. Terence East's manual appears eight years after the first. It is particularly welcome, for it is the most practical, up-to-date, and well-balanced short book on the subject. The war years have seen important new developments in the therapy of cardiovascular disease, and in this volume will be found reference to thiouracil, to ligation of the patent ductus, and even to the extensive sympathectomies still under trial for hypertension. In spite of the limited scope of the book—it has only 191 pages—the author has found room for consideration of certain problems commonly encountered in general practice, such as heart conditions in the middle-aged and elderly, the relation of heart disease to pregnancy, the question of athletics, and lesions of the peripheral arteries and veins. Dr. East has naturally omitted any treatment of electrocardiograms from a work of this size, but he gives an account of the indications for the use of this instrumental method of investigation and the kind of information to be gained from it. By economy of phrase and avoidance of theoretical discussion

a readily understandable and practically useful work has been achieved and certainly many practitioners of medicine will derive from it help in both diagnosis and treatment.

HEALTH INSTRUCTION

Health Instruction Yearbook, 1945. Compiled by Oliver E. Byrd, Ed.D. Foreword by Walter H. Brown, M.D. (Pp. 344. \$3.00 or 18s. 6d.) California: Stanford University Press; London: Oxford University Press.

This year book, compiled by Prof. Oliver E. Byrd, is the third annual volume of the series, and is intended for teachers, students, doctors, nurses, and others concerned with problems of health. It consists in an analysis of 316 articles which have appeared in various American scientific journals during the twelve months preceding publication, and it forms a readable and instructive reference book.

In the introductory chapters, which relate to health as a social problem, it is maintained that inhabitants of the U.S.A. are "far away the best-fed people in the world," and that their average length of life in 1943 was 64½ years. The chapter on nutrition describes in considerable detail the recent investigations on vitamins, especially on the vitamin-B complex. Diets deficient in this vitamin cause men first to lose their willingness and then their ability to do hard physical work. The chapter on heredity discusses the Rh factor, and records the opinion of one investigator that the discovery of the factor in 1940 is perhaps the most significant single discovery hitherto made in medical genetics. It is stated that 11% of all the marriages in the U.S.A. are potentially dangerous in terms of incompatibility (father Rh-positive and mother Rh-negative). The chapter on infection and immunity refers to the unique law passed in 1943 by the State of Alabama which requires all civilians between the ages of 14 and 50 to have their blood examined for syphilis. In the three counties in which the blood-testing programme has been completed, 2.2% of the whites and 20.5% of the negroes were found to be infected. One investigator points out that the world "missed the boat" by almost seventy years in respect of the insecticide D.D.T., the use of which would have saved millions of lives. It is maintained that, under American development, it has proved to be one of the greatest medical advances of the war and possibly of all time.

Subsequent chapters of the book deal with such topics as diet-forming substances, safety, family health, school health, occupational health, and there is a final chapter on trends and possibilities. This is of special interest at the present time as it discusses the Wagner-Dingell Bill, which was introduced in Congress in May, 1945. Its provisions include compulsory health insurance for all persons covered by Social Security, and a 10-year Federal State maintenance of hospitals, health centres, and clinics.

PRINCIPLES AND PRACTICE OF SURGERY

Principles and Practice of Surgery. By W. Wayne Babcock, M.D. With the collaboration of members of the Faculty of Temple University. (Pp. 1,331; 1,141 engravings and 8 coloured plates. 60s.) London: Henry Kimpton.

Wayne Babcock is a surgeon with an international reputation, and his *Textbook of Surgery* was widely known and appreciated. Using this book as a basis he has now produced, with the help of 37 collaborators, an enlarged book entitled *Principles and Practice of Surgery*. All these writers are members of the Faculty of Temple University, Philadelphia; by thus choosing his team from a single school the chief author has tried to avoid the duplication and confusions so commonly found in books of multi-authorship. The volume is intended to "supply the student and practitioner with a working knowledge of common and rare surgical conditions occurring not only in the United States but throughout the world."

Viewed in a broad way it may be said that the book fulfils its object in its 1,300-odd pages, but we cannot help feeling that the inclusion of so many rare diseases has led to serious curtailment of the space available for the commoner conditions, and so one gets the impression of a lack of balance. Thus although such conditions as the Klippel-Feil syndrome, Hand-Christian-Schüller disease, polyostotic fibrous dysplasia, receive attention, Russell's viper venom is not mentioned in the treatment of haemophilia, nor excision of the patella in the treatment of fracture of that bone, nor Helfet's aluminium acetate treatment of osteitis deformans—yet these are much

commoner conditions. One could cite many more examples where common conditions are inadequately described and dismissed in a short paragraph while rarer diseases receive more attention. There are also places where the language is ambiguous (a serious defect in a book intended for students), and there are uncorrected misstatements. For instance, in discussing post-spinal headaches it is noted that they have been ascribed to a dural leak "proved not to be due to sharp needles"; the uninitiated may well inquire what this really means. Then lymphopathia venereum is differentiated from lymphogranuloma inguinale, though on the preceding page they are said to be synonymous. The freezing point of sea water is given as 1.9° C. in a description of immersion foot there is no mention of neurectomy in the treatment of Morton's metatarsalgia; thiouracil is not noted for thyrotoxicosis (but there is a reference in the bibliography); and Pancoast's name is mentioned but not his disease.

All these are perhaps rather small points, but they are deliberately noted here to show that the book needs rather more careful editing; the certainty of further editions will provide an opportunity for this. There is, however, a lot more to be said in favour of the book; in particular those sections which contain Dr. Babcock's personal contribution—e.g., rectal and vascular surgery—can be praised. The illustrations (there are over a thousand of them) reach a very high standard and are exceptionally useful—the few coloured plates are among the best we have seen, and the reproduction of all is beyond criticism. Indeed the whole format is good, and there is a forty-page bibliography and a full index (so essential in a book of this character) at the end.

To sum up, our impressions are that the book is a very fine production; the editor has made a valiant attempt to reduce the whole of surgery, including all its aspects such as operative technique, materials, etc., into the compass of a single volume of reasonable size. If the effort has not been 100% successful it is due to the enormous scope of modern surgery rather than to any defect on the part of the authors.

Notes on Books

A small book, *Curare-Intocostin*, published by E. R. Squibb and Sons, New York, contains a very useful account of the recent literature on curare, and in particular of its use in shock therapy and in anaesthesia. Intocostin is an extract of curare which is standardized by a method said to be very accurate, but which appears from the description given to be a rough method only. The solution is injected slowly into the ear vein of a rabbit and a dose is determined which just prevents the animal from raising its head; this dose is expressed per kg. body weight. This is the only information on this very important matter which is given in a book of 291 pages. There is no statement of the number of animals used, and no evidence presented to indicate the accuracy attained. This is a serious omission. The need for curare in shock therapy is considerable; thus Easton and Sommers state (*J. nerv. ment. Dis.* 1944, 99, 236) that in a series of 800 cases treated with metrazol (leptazol) there was a fracture incidence of 26%, and that in the 209 cases of fracture 535 vertebral bodies were involved. It is therefore not surprising that they think that curare should always be used as a supplement. The maximum curare effect is reached in two minutes after intravenous injection. The best dose is one which produces weakness of the neck muscles so that there is great difficulty in raising the head from the pillow. After a smaller dose there is insufficient protection of the long bones and spine, and after a larger dose there is respiratory arrest.

Introduction to Present Day Psychology. By Dr. CURT BOENHEIM (Staples Press, Ltd., 12s. 6d.) is based on 24 lectures given under the auspices of the W.E.A. in Reading University. Prof. Wolters in a foreword praises its clarity of writing and its eclectic approach. The author has naturally paid greatest attention to his own work in child guidance, dealing at length in the first part, "Psychology," with play, perhaps to the detriment of other highly important subjects, and in the second part, "Applied Psychology," with child guidance, leaving other chapters on psychiatry, general medicine, industrial psychology, and delinquency to be sketched in somewhat perfunctorily. On the whole the book is free of technicalities, except in the chapters dealing with the psychological theories of Freud, Jung, and Adler, where it is inevitable that some technical terms should be used. For those who wish to learn anew something of this complicated subject Dr. Boenheim's introduction is to be commended.

NEW AMERICAN ANTIMALARIAL
COMPOUNDS

paludrine is the new British antimalarial compound.¹ Now that the wartime censorship has been raised it is possible to describe the new American antimalarials. When Japan entered the war and supplies of quinine were cut off a search for new compounds was begun under Government auspices on the vast scale congenial to our transatlantic neighbours. More than 14,000 compounds were examined at a cost of almost £2,000,000. During this work much knowledge was gained about the best ways of using mepacrine (atebrin) and about the biology of the malaria parasite. The main attention of the American investigators, however, was directed to the finding of new and better antimalarial compounds; the results of their work are now being made public, and two types of drug show particular promise.

The first group includes chloroquin, or resochin, also known as SN 7618, which is 7-chloro-4 (4-diethylamino-1-ethylbutylamino) quinoline.

This compound has an interesting history. When the Allied Forces occupied Tunis in 1943 they found that a secret German preparation called sontoquin (later renamed 11) had been sent there for trials against malaria. Workers at the I.G. Farbenindustrie had synthesized sontoquin before the war; but it was considered to be little better than mepacrine, and its further development was conducted half-heartedly. Supplies of sontoquin were taken to America and Britain, and the chemical formula was determined. Clinical trials in the U.S.A. of one of its derivatives—chloroquin—showed that it had important advantages over mepacrine. Large-scale trials confirmed this; mass production was begun, and if the war had continued another year chloroquin would probably have displaced mepacrine as the main antimalarial in use among the American Forces. Its absorption, excretion, and distribution in the body resemble those of mepacrine, but it is colourless and does not stain the skin. It completely suppresses malignant tertian malarial infection, and adequate treatment of clinical attacks produces radical cure with complete elimination of the parasites from the body.² All

signs of benign tertian infection are suppressed so long as administration of the drug continues, but when this ceases relapse usually occurs. In order to suppress malaria in soldiers it is necessary to give 0.1 g. mepacrine every day. The same results may be obtained by giving a single dose of 0.25 g. chloroquin weekly, which is important as reducing the time-consuming supervision of drug-administration to one-seventh of its previous level. In its general properties chloroquin challenges comparison with paludrine. One or other of these two compounds will almost certainly replace quinine and mepacrine; comparative tests in field trials are now taking place. Chloroquin has been tried on a much wider scale than has paludrine, but in many ways paludrine seems to be the more promising of the two.

Neither chloroquin nor paludrine can effect a radical cure of benign tertian malaria. All clinical symptoms disappear during administration of either drug, but on withdrawal a relapse usually appears sooner or later. It is hoped that radical cures will be brought about by means of another new American compound—SN 13276. In 1943 there was much controversy over the merits of pamaquin (plasmoquin). Earlier work by Sinton in India had suggested that a combined course of pamaquin and quinine was more effective than any other remedy in sterilizing benign tertian infections. Owing to the absence of controls this work was open to other interpretations, and in addition pamaquin was unpopular because it was apt to produce toxic reactions. The Malaria Committee of the Medical Research Council instituted comparative trials of pamaquin plus quinine and of mepacrine. These investigations were carried out by Kelleher and Thompson. They were statistically satisfactory, and the cases were followed up successfully. During the following six months about 30% of the patients treated with mepacrine relapsed, as against only 10% of those treated with pamaquin and quinine. This proof of the value of pamaquin was communicated to the American workers, who instituted a very extensive study of the plasmoquin (8-aminoquinoline) series of compounds to find a more active but less toxic derivative. The most promising compound to emerge from this study is SN 13276.

Therapeutically it is as active as pamaquin in avian infections but is less than half as toxic to laboratory animals. In man a thrice-daily dose of 20 mg. SN 13276 is as well tolerated as 10 mg. pamaquin given in the same way. Volunteers in an American prison who were infected with the virulent South-West Pacific strain of *P. vivax* and treated with full doses of the new compound (plus quinine) appear to have been completely freed from the infection. Further trials are being undertaken in the U.S.A. and in Britain; until these are completed it is not possible to make a true assessment.

¹ *British Medical Journal*, 1946, 1, 919.

² *J. Amer. med. Ass.*, 1946, April 20.

The war has caused much suffering and destruction. It has, however, led to great improvements in our means for controlling and treating malaria. The scientific skill and the capital invested in the American wartime programme of malaria research will yield a good dividend of improved health in the years to come.

DISABLED PERSONS ACT, 1944

In last week's *Journal* Sir Reginald Watson-Jones drew attention to the recent Order of the Minister of Labour that the quota of disabled persons employed in industry shall be raised from 2% to 3%. Sir Reginald points out that this increases the number of disabled persons to be employed by 150,000. He also states that this is an answer to the criticism made in a recent leading article¹ that the "typical Civil Service approach to the problem . . . does not even achieve its object, since it merely means that the 2% will be made up of those with flat feet and subject to bronchitis." This statement was meant to illustrate one of the snags of the Disabled Persons Employment Act and to exemplify what, in fact, is happening apparently in many factories.

Under the Disabled Persons Act, 1944, a register of disabled persons is kept at the local offices of the Ministry of Labour and National Service. The main condition for registration is "a substantial handicap to employment and work which is likely to last for at least six months." All employers with 20 or more workers are required to employ a quota of registered disabled persons—formerly 2% and now 3% (incidentally, 2-3% of 20 is an awkward kind of person to employ). "An employer," to cite from the report of the B.M.A. Rehabilitation Committee,² "who has less than his quota may not take on a non-registered person without a special permit from the Minister, and a registered disabled person may not be discharged from his employment without reasonable cause if the discharge would bring the employer below his quota." Vacancies in certain occupations specially suited for disabled persons may not be filled by unregistered persons without a permit from the Minister. The larger industries have always found employment for disabled employees and have gone to much trouble to fit the job to the man. The variety of processes in a large industry facilitates this. In this country the small factory is the rule and the large factory the exception. The employer of, say, 250 men or fewer has a smaller variety of jobs to suit different forms of disablement and is, moreover, reluctant to have his labour controlled by a Government Department. He wants, in other words, to choose his own man for the job to be done. In order to avoid what he regards as the danger of having labour dumped on him the small employer has in many instances sought to satisfy his quota of disabled employees out of persons already working for him. For example, a man may be doing a whole-time job satisfactorily in spite of the disability of a hernia controlled by a truss: he can now qualify for the register. Such examples could be multiplied. By encouraging such workers to be registered

the employer is doing something which is humanly understandable but does not contribute to the solution of a difficult problem, and once one employer in a big industrial area starts doing this other employers follow suit. This, at least, seems to be the experience of practitioners working in industrial areas, and it serves no purpose to blink the fact. The reaction of the Ministry of Labour is to increase the quota, and it presumably can go on increasing the quota until it achieves its aim. If we are to be fair to the employers we should recognize that their objection is not to the employment of disabled persons but to what they regard as possible interference with their selection of labour. There is, in fact, a problem, and we suggest that it will not be solved by stepping up the percentage of employed disabled persons.

The hard core of the problem is the employment of those whose disablement is so serious that economic employment is difficult to find. In one form of disability—namely, tuberculosis—a solution has been found in the Papworth Village Settlement. The Ministry of Labour has established the Disabled Persons Employment Corporation, which has now been in existence for a year. No doubt building and other obstacles have made it impossible for the Corporation to set up more than three factories in this time. It is, nevertheless, only a small beginning, and we may hope to see a more ambitious programme unfolding during the next twelve months. Such a development is surely the real solution to the real problem at a time when every available ounce of manpower is needed if this country is to hold its own in a world rapidly becoming industrialized. In the meanwhile we may note with satisfaction that Disablement Rehabilitation Officers are now receiving medical training in hospitals in London and in Manchester and that Regional Consultants have been appointed to supervise the results of their work. We would repeat the final sentence of the leading article in the *Journal* of June 29: "Perhaps industrial medicine will be judged more on its success or failure in placing individuals in industry than on any other aspect of its work." If the Rehabilitation Service is to succeed then it must be based on the principles formulated by the B.M.A.'s Rehabilitation Committee—namely, (1) Unity of control at the centre, (2) Unity of control in the region, (3) Continuity of care, (4) Effective liaison between general practitioner, hospital staff, and industrial medical officer, (5) Co-operation between medicine and industry, and (6) Close contact between hospitals and rehabilitation centres, convalescent homes and vocational training centres.

H. G. WELLS

One of the curious things about the tributes to H. G. Wells in the days after his death was the range of ages of the men who said how profoundly he had influenced those of their generation. Men in their early forties and men in their early seventies said the same thing. It was a remarkable testimony to a man who throughout a long life retained a youthful zest for living and learning and teaching. For Wells was a teacher as well as a prophet. He possessed that rare quality among teachers—an intense desire to make other people think things out for them

¹ *British Medical Journal*, 1946, 1, 990.

² *Supplement to the British Medical Journal*, 1946, 1, 189.

lives, not to accept the edicts of authority without challenge. Wells was the great challenger.

The medical profession owes him much, if only for his insistence on the importance of biology. An educational stem that neglected biology was for him an infuriating anachronism. It was symptomatic of his function as a teacher that *The Outline of History* was followed by *The Science of Life*: the story of man and then the story of living things. These two volumes—the second written in conjunction with his son, G. P. Wells, and Julian Huxley—gave the growing mind a “world picture.” And for Wells any mind worth anything was always growing. He had little sympathy with the sterile pessimism of the twentieth century intellectual who croaked disaster with morbid elish. Yet he foresaw the possible eclipse of the species *Homo sapiens* if man lost his adaptability, and was aware of the parallel of the reptiles which lost their position as the foremost animals of the earth in the Mesozoic period.

In relation to the medical profession Wells was the antithesis of his contemporary, Bernard Shaw. “I do not like waiting medical men,” he wrote in a preface to a book written by two doctors. “My friend G. B. Shaw does.” His scientific training and profound interest in biology saved him from the facile attacks so often made on doctors by men whose gift for the pen is equalled by ignorance of that branch of applied biology which we call Medicine. Wells was aware of the ambivalent attitude of the sufferer to the healer. “It is in the nature of man,” he wrote, “to be rebellious against his medical director.” Yet he did not hesitate to criticize when he felt that criticism was called for. He thought the medical profession erred in being reluctant to listen to the unorthodox healer. “One other conspicuous fault the medical profession has, it does not advertise.” By this he did not mean personal advertisement. “But I think that it might respond much more generously and effectively to the common desire to know what is being discovered, what is being practised and why.” The alternative to this secret conspiracy on the part of the medical profession was, as Wells saw it, “a vast amount of misleading pseudo-information in the press that simply fertilizes the soil for the advertisements of patent specifics.” And he added this to his store of wise sayings: “Communicative doctors make intelligent and helpful patients, and the more that treatment becomes collaboration the better for both practitioner and client.” Wells suffered from diabetes, and it was characteristic of him that he identified himself with the interests of the Diabetic Association so that doctors and diabetics could collaborate the better. Already over 70, he took his D.Sc.Lond. with a thesis “On the quality of illusion in the continuity of the individual life in the higher metazoa, with particular reference to the species *Homo sapiens*.”

“H.G.,” as he was known to a multitude of friends, hated cant and pomp and reverence for authority. This extraordinary man saw himself as the ordinary man writ large—a man with a passionate desire that all other ordinary men should see life in all its intricacies with the same dazzling clarity with which he saw it.

CAVAL LIGATION FOR THROMBOPHLEBITIS

When pulmonary infarction follows thrombophlebitis in a lower extremity, it is always tempting to close the door to further embolism by femoral ligation. Since, however, it is usually not the frankly thrombosed limb that is the source of the pulmonary embolus but its apparently more normal fellow, it is wise, if ligation is done, to tie both femoral veins. Even this is not a final solution of the problem of embolus prevention, for often, at the time when operation is performed, the thrombotic process has already extended into the pelvis, and would require ligation of the common iliac, which Homans¹ has indeed advised and performed. Logically, the most satisfactory site of ligation for the prevention of embolism would be at a level above the confluence of the veins of the two lower limbs, but the surgeon's hand is stayed from caval ligation by fear of its danger. In cases of repeated infarction from puerperal pelvic thrombophlebitis the conflict between desire to establish caval occlusion and dread of its consequences is particularly sharp.

Lower,² in 1669, showed that experimental caval ligation is fatal if performed above the entry of the renal veins, compatible with life if performed below that level. In 1911 Pleasants³ recorded 8 cases of caval ligation, and Ochsner and DeBakey,⁴ in 1941, were able to comment on 48, performed chiefly for puerperal pelvic thrombophlebitis. Collins, Jones, and Nelson⁵ reported 41 cases of pelvic thrombophlebitis proved at operation or at necropsy; in 8 of these the inferior vena cava was ligated, with one death. Gaston and Folsom⁶ have described in detail two cases of thrombophlebitis of the lower extremities in which the inferior vena cava was successfully ligated. Both patients suffered from a mottled cyanosis and from venous distension of the lower limbs for a few days after operation, and from a pitting oedema of the legs. In the case of one patient, a woman of 49, the oedema resolved completely after four months; in the other, a man of 71 with calcified arteries in the lower limbs, a minimal oedema persisted for three months. In the second case, the pressure in the veins of the foot was measured at intervals after the ligation; on the third day after operation it was 380 mm. of water, falling to 300 on the fifteenth day.

It seems usual, therefore, for the collateral venous circulation to compensate for a ligated inferior vena cava. But the operation is likely to be regarded only as a last line of defence in patients who suffer from thrombophlebitis associated with frequently repeated pulmonary embolism. The selection of suitable patients remains a matter of the greatest difficulty, and opportunity for the justifiable performance of caval ligation will seldom arise. To sustain the patient during the dangerous early post-operative period, when the venous collaterals are strained to capacity, Gaston and Folsom recommend swathing of the feet, tight elastic bandaging of legs and thighs, the early use of oxygen, and adequate plasma replacement of the oedema fluid, which may be rapidly withdrawn from the circulation after the ligature is applied.

PERIPHERAL NERVES IN PERNICIOUS ANAEMIA

It is well known to neurologists that changes may occur in the peripheral nerves in cases of subacute combined cord degeneration, and that treatment may be followed by clear-cut clinical improvement. The extent of these

¹ Surg. Gynec. Obstet., 1944, 79, 70.

² Tractatus de corde, 1669, London.

³ Johns Hosp. Rep., 1911, 16, 363.

⁵ Med. Surg. J., New Orleans, 1943, 95, 375.

⁶ New Engl. J. Med., 1945, 233, 222.

changes and the frequency of their occurrence have been debated. We read in the outstanding paper by J. S. R. Russell, F. E. Batten, and J. Collier¹ that there were severe peripheral nerve damage in one case, mild changes in two, but no abnormality in three others. J. G. Greenfield and E. A. Carmichael² removed portions of the anterior tibial nerves of living patients with pernicious anaemia, and found a reduction in the myelin sheaths, particularly around the large nerve fibres. Probably the earliest reports of such peripheral changes were those made by C. van Noorden³ and by Eisenlohr.⁴ A recent paper by J. B. Dynes and J. W. Norcross⁵ has put the incidence of peripheral nervous lesions at about 23%. Still more recently, D. B. Foster⁶ found degeneration of peripheral nerves in the post-mortem study of four fatal cases of subacute combined spinal cord disease, and in the biopsy examination of one further case. As might be expected, the changes were less in those cases in which liver extract had been administered. The last observation illustrates the great regenerative capacity of peripheral nerves. In this connexion we may also note the findings of C. Berry, C. Neumann, and J. C. Hinsey,⁷ who found that in experimental cases injured nerve trunks were capable of regenerating normally, even in the presence of a severe thiamine deficiency.

PENICILLIN IN BRONCHIECTASIS

The success of resection of the lung for bronchiectasis confined to one or more lobes emphasizes the unsatisfactory nature of the treatment available for patients with bronchiectasis of less favourable distribution. It is not surprising, therefore, that the efficacy of penicillin in a variety of infections should have raised hopes that it might be of value in these cases. Preliminary work by Mutch and Rewell⁸ has shown that inhalation of the mist produced from solutions of penicillin by a nebulizer can cause a bacteriostatic concentration of the drug in the blood. An even more effective concentration may be produced by this means at the surface of the respiratory mucosa. The results obtained by penicillin therapy in bronchiectasis vary from case to case and even in favourable cases may not be long lasting. The bacterial flora of bronchiectatic cavities includes potentially pathogenic organisms sensitive to penicillin—for instance, *H. influenzae* and some of the Friedländer group; and in chronic infections organisms previously sensitive may become penicillin-resistant. Moreover, intercurrent respiratory infections, epidemic or otherwise, might be expected to undo any good results obtained by penicillin treatment.

Bobrowitz, Edlin, Bassin, and Woolley⁹ have recently published a preliminary report on the treatment of 12 patients with multilobar bronchiectasis. Penicillin was applied in a variety of ways: by intratracheal injection after local anaesthesia of the larynx, by the inhalation of nebulized solutions, by intramuscular injection, and by combinations of these methods. Intratracheal injection twice a day of a dose varying from 50,000 to 150,000 units, dissolved in 10 to 20 ml. of saline solution, resulted in a very high penicillin concentration in the sputum, and a concentration in the urine which indicated in one case that over 30% of the total dose had been absorbed, but a low and variable concentration in the blood. After inhalation the concentration in the sputum, though bacteriostatic,

was much lower, and penicillin was demonstrated in the blood inconstantly and also at a much lower level than was found by Mutch and Rewell. The duration of treatment varied from four days for some of the patients treated by intratracheal injection to 115 days for one still under treatment by both this method and inhalation. The clinical results were claimed to be favourable. In 9 of the 10 patients whose sputum was foul before treatment the odour cleared up within a few days of beginning any form of penicillin therapy. It returned soon after the cessation of treatment in most of them, and in the two cases in which the sputum remained free from odour the follow-up was no more than one month. The volume of sputum was considerably reduced during treatment—in most instances by more than 50%. Bacteriologically the data are rather incomplete. As expected, the number of Gram-positive organisms and of pus cells diminished considerably during treatment, but usually increased again when treatment was discontinued. The authors recognize the frequently transient nature of the improvement observed but suggest that long-continued inhalation may help some chronic cases of bronchiectasis. They stress also the probable value of intratracheal penicillin as a preparation for lung resection in bronchiectasis.

An aspect of this problem which may merit further investigation is the possibility of help from penicillin in those cases of bronchial dilatation associated with pulmonary atelectasis, which have been shown to be reversible if the atelectasis can be relieved before the bronchi have been permanently damaged by infection. In any case which may fall into this group the result of intensive treatment by continuous postural drainage and breathing exercises must be observed before the condition is pronounced to be a permanent bronchiectasis. It may be found that penicillin by inhalation, or by intratracheal injection, is a valuable addition to the therapeutic measures available to the physician faced with a problem of this sort.

THE HOSPITAL "DOMESDAY BOOK"

The surveys of Hospital Services in England and Wales, which have lately been published in the form of Blue Books and have been reviewed from time to time in these columns, are summarized in a booklet issued by the Nuffield Provincial Hospitals Trust and printed at the Oxford University Press. It is not an easy task to condense into 20 short pages the work of ten teams of surveyors, but by representative quotations it is shown that the surveyors, all of them men experienced in hospital work, either on the clinical or on the administrative side, were virtually unanimous on three main defects in hospital services—namely, inadequate accommodation, shortage or ill-distribution of specialists, and lack of co-ordination. Not all the surveyors commit themselves to estimates of deficiency of beds in their areas, but, by applying to the three areas where no estimates are given the average of the other surveyors, the conclusion is reached that the total estimated deficiency for all classes of beds—acute general, maternity, tuberculosis, infectious diseases, and chronic sick—is approximately 98,000. If infectious disease beds are left out of the reckoning—and there are surpluses in many areas in this category—the existing total of 225,000 beds needs to be increased by more than 40%. The fact that available beds fall short by about one-third of the estimated total of accommodation required raises the question how far the State will be able to meet immediately the newly assured right of all the population to hospital treatment.

HEALTH IN H.M. PRISONS

The report of the Commissioners of Prisons and Directors of Convict Prisons for the years 1939-41* departs considerably from the form of its predecessors, for it covers a period of unprecedented difficulty and disturbance. As the summer of 1939 wore on the preparations for meeting enemy attack were amplified and the prison populations were moved from areas judged to be specially liable to attack. Over 2,000 prisoners and Borstal inmates, with the whole of their personal property and records, were transferred in three days almost without incident. When the expected air raids did not come and the normal inflow of prisoners continued, the drastic adjustments necessary had a disturbing effect on the discipline of some provincial prisons. The sudden influx, when the danger of invasion became acute in 1940, of many hundreds of alien internees and of persons detained under Regulation 18b presented problems which, in their novelty, multiplicity, and urgency, were for a time almost overwhelming. The prison staffs had to keep these persons separate from ordinary prisoners and apply different rules to them, to take care of large quantities of miscellaneous and sometimes valuable property, and also to struggle with the language difficulty. The air raids threw a heavy burden on all members of the staffs and tested their courage and endurance to the utmost. Liverpool prison had eight direct hits in one night and was evacuated, and few other prisons escaped damage and casualties. The behaviour of the prisoners locked in their cells was on the whole remarkably good. Against the inevitable feeling of helplessness was set the fact that a prison cell is one of the best forms of air-raid shelter. During the years under review thirty-nine men and four Borstal boys were killed by enemy action—a small proportion of a total population that was never below 8,000.

The Medical Commissioner, Dr. J. C. W. Methven, reports a sharp increase in the number of deaths in local prisons from natural causes. Of the twenty-seven deaths that occurred in 1939, most were caused by serious heart disease and cerebral haemorrhage. As he points out, many prisoners are suffering on admission from neglected chronic ailments, which are made worse by their method of living and which lower their resistance to acute illness. This being so, it is surprising that the death rate in prisons remains lower than that of the population as a whole. In 1941 five men committed suicide, but there were no special features about the cases and the Medical Commissioner believes that the increase in number was fortuitous.

The number of persons remanded to prison for mental observation has increased very considerably. Prison medical officers are well qualified for this work and welcome it, but it necessitates many hours of patient investigation. Dr. Methven repeats the request made in previous reports that magistrates' and justices' clerks should assist medical officers by sending the fullest particulars of the prisoner and their reasons for wanting a report. All too frequently they send nothing more than a request that the prisoner be kept under observation and a report submitted at the end of the remand period. The number of persons certified insane in local prisons shows a steady decrease, which in the Commissioner's opinion bears some relation to the increase in the number of cases remanded for mental observation. The number of prisoners in convict prisons treated in and out of hospital shows a steady decline, and he believes that payment for work and the greater interest shown in prison industries are largely responsible.

Special Problems

The Medical Commissioner regards it as unfortunate that statistics of the incidence of venereal disease and body infestation were not collected after 1925. They would have been invaluable during the early war years. They are now being collected, however, and will be published in future reports. Much attention is paid to venereal disease, and infected prisoners are carefully treated by modern methods. The number of women prisoners requiring treatment for infested heads has increased substantially, and the depleted nursing staffs have done much hard work for which they deserve praise.

Many medical activities unfortunately came to an end when war broke out. The medical department particularly felt the

closing of the surgical unit at Wormwood Scrubs, where Mr. G. O. Chambers had performed an impressive list of operations in 1938-9. If possible, prisoners requiring surgical treatment were sent to outside hospitals; where this could not be done the small theatre at Lewes prison was used. Similarly, the psychiatric work at Wormwood Scrubs ceased with the transfer of Dr. W. H. de B. Hubert to the Army and Dr. H. T. P. Young to another prison. Some medical officers with special qualifications for psychiatry tried to assist prisoners, but in spite of their efforts psychiatric treatment virtually ceased. It has since been resumed, and Dr. Methven promises an account of the work in the next report.

When civilian rationing was introduced the whole scheme of prison dietary was recast; instead of an arrangement of set meals, a ration scale was drawn up for each prisoner in strict accordance with the civilian ration scale. The change was an improvement on the whole, for the addition to the rations of such adjuncts as curry powder, herbs, and dried fruit, or fresh fruit in season, enabled the cooks to serve the rations in more palatable form and with greater variation. Few complaints have been received from prisoners, and their general health and body weight have been maintained. The work of reconditioning and improving kitchens has gone ahead, and the standard of meals has improved.

U.N.R.R.A. ACTIVITIES

Czech Psychiatrist's Study Tour

U.N.R.R.A. is sponsoring an effort to introduce into some European countries which were shut off from contact with Western medicine during the war a knowledge of recent medical progress. One example of this in the field of psychiatry is the recent visit to this country of a Czech psychiatrist and neurologist, Dr. Eugen Vencovsky, of Pilsen, who has been spending six weeks in Great Britain as the guest of U.N.R.R.A. studying the more advanced methods now employed in mental hospitals. From this country, under the same auspices, he has gone to Paris for two weeks and to Zurich for one. His time here was spent mostly at Crichton Royal, Dumfries, and at various mental hospitals and clinics, including the Maudsley, in and around London. He was also enabled to attend the recent annual meeting in Edinburgh of the Royal Medico-Psychological Association. Dr. Vencovsky has taken the opportunity of studying particularly recent methods of neurosurgery. He explains that with the invasion of Czechoslovakia early in 1939 all work of a research or experimental character in mental hospitals was forbidden, and psychiatrists, like others, were restricted to the routine medical service. They had no opportunity of extending their knowledge. Having studied developments in this country, Dr. Vencovsky is returning to acquaint his colleagues in Czechoslovakia with his observations.

Medical Help for Yugoslavia

A country in which U.N.R.R.A. has carried out some of its most intensive work is Yugoslavia, and the results of it are now visible in a lessening of child malnutrition and disease. Dr. Eleanor Singer, a young London practitioner who attached herself to U.N.R.R.A. two years ago for work in Yugoslavia, has lately returned on leave from Sarajevo and described some of her experiences at an U.N.R.R.A. press conference. She stated that the number of war orphans in Yugoslavia was computed at 88,000, and that there were in addition nearly half a million children who had lost one parent. In Bosnia rickets was almost universal, and to this was added dysentery and other intestinal infections, as well as tuberculosis—a state of affairs which, when combined with a shortage of foods, drugs, and beds, heavily weighted the scale against the sufferers. Much has already been done, however, to ameliorate the situation. In Sarajevo alone there are fifteen orphanages, and at these and at the clinics Yugoslavian girls and women are being trained particularly in maternal and infant care. Maternity homes have been established in which homeless women are taken a month before their confinement and kept for at least three months afterwards, during which time they are instructed in the care of their children and also, if illiterate, are given some primary education.

Correspondence

Health Service Bill

SIR,—The Health Service Bill, having passed its Third Reading in the House of Commons, can suffer no alterations of its text unless, as is improbable, the Lords pass amendments, which again have to secure the assent of the Commons. In these circumstances I submit that any further "negotiations" are futile. The sole decision to which the profession must come is whether or not they, as individuals, will accept service under the Act. I derive the most encouragement in the present position from the concluding words of the Minister (*Hansard*, July 26, 1946, columns 475-6). He said that "without the co-operation of the great medical profession the scheme is bound to fail," and he at last realized that "the House of Commons only passes Bills but it is the men and women outside who can make them living realities." He has seen the red light.

I have received during the last few days a statement from a surgical colleague in Canberra which gives the following information as regards the position of the medical profession in Australia, faced with exactly the same menace as confronts us now. He writes (July 7, 1946) that an Act embodying the socialist aspirations for a State Medical Service was passed some years ago by the Socialist Government. "Although passed, it was never brought into operation (the italics are mine), the most important reason being that the doctors woke up to the threat to their freedom and repudiated, and almost broke up, the B.M.A., which had negotiated an agreement, secretly, with the Government. . . . The reaction was such that a Royal Commission was appointed to consider the whole matter, but the Act was dropped without a report being published."

Another attempt was made later by indirect methods. "An Act was passed which gave the Minister power to enter into contracts with doctors to provide medical services. This power really made the Act an Enabling Act on which a socialized medical service could have been built up by regulation. The Victoria Branch of the B.M.A. challenged the Act and the High Court found it *ultra vires*."

The Australian Socialist Government is, I submit, much more firmly established than our present Socialist Government. The profession in Australia is, I further submit, less well organized than here. The B.M.A. has now enlisted practically the entire active profession in its membership, precisely because the profession wishes to present a united front in refusing to accept service in the conditions threatened by the Bill. The Representative Body has given the clearest lead on policy to the Council, and the fullest authority to the Chairman to make the statement which he is recorded as having made at the meeting: "Now we have come to the time when one side or the other is to give way. A conflict is inevitable. The matter is entirely in our own hands; there are no other doctors but doctors who are qualified. We are in the strongest possible position for ensuring that what we think is best for the public will be carried out."—I am, etc.,

House of Commons.

E. GRAHAM LITTLE.

SIR,—May I give my support to the proposals outlined by Dr. Victor Russell (June 1, p. 846) and Flight-Lieut. J. H. Bergin (Aug. 3, p. 176)? The latter asks why has the New Zealand scheme never been really publicized. The answer must lie with the Medical Planning Committee who never thought fit to bring it to the notice of the profession as a whole.

B.M.A. policy towards the National Service Bill must have been formulated from information furnished by the canvass carried out by the Institute of Public Opinion. I well remember that no opportunity was given then for expressing views on an alternative medical service. It has been taken for granted all along that general practitioners were well satisfied with the panel system and would only accept some extension of this to include dependants. But, I ask, is this really so? Up to date most practitioners have earned as much and often much more than their panel fees by private practice, and are now coolly asked to give this up. Anyone with experience of colliery practice knows what this means—crowded surgeries in which it

is impossible to practise even the rudiments of medicine. If this is the type of freedom envisaged by Principle A then I consider it largely illusory and not worth taking strong action against the Government for.

It has been forgotten that the capitation system was only accepted under protest in 1911 as the only workable makeshift to cover a section of the population who were unable to pay a doctor for attendance previously. I feel sure that we should all work better if we felt we were being paid for each item of service rendered, or in other words for the work we actually do. The duty of the Government is to assist the public to have the best medical attention regardless of lack of means, and this is assured by the New Zealand scheme without controlling the medical profession or the wage earner. If at this stage we refuse to work the National Service Bill and offer only private practice as an alternative we thereby hit the working man very hard. He will not be able to have attention unless we are prepared to give it gratuitously. There is nothing immoral in paying for what one gets, and to my mind it does ensure that the patient-doctor relationship is preserved in a manner quite impossible in the so-much-a-head system.

There is now to be a referendum or plebiscite of the profession. I call upon the B.M.A. Council to include in their questionnaire a request to every practitioner asking which he prefers: a capitation system, a salary, or payment per item of service as under the New Zealand scheme. Doctors unfamiliar with the latter have seen a similar scheme in a small way in payments for service under the Midwives' Act. So far I have not heard any adverse criticism of this scheme.—I am, etc.,

St. Asaph.

A. H. HOLMES.

* "General Practice in New Zealand" appeared in the *Supplement of Nov. 18, 1944* (p. 115); "In New Zealand To-day" was published on Aug. 11, 1945 (p. 42); and "Free Hospital Experience in New Zealand" on Sept. 22, 1945 (p. 70).—Ed., B.M.J.

SIR,—The National Health Bill has now had its Third Reading in the House of Commons. This means that there is no possible chance of any major modification, and it means a good deal else besides. First, that the British Medical Association, now led by my friend Dr. Guy Dain, has once more proved itself a dismal, useless failure; the Minister of Health quite obviously never intended to negotiate, was never interested in negotiation, and merely carried out the policy of his party. Given an adequate majority Pink Socialism dictates just as much as Red Russia. In the second place it means very considerable changes in the future. The number of general practitioners will have to be very considerably increased, both in order to cope with the great increase in calls on their time, and with the number of consultations and the number of certificates which will be required under the new Act. Thirdly, at least three times as many consultants and specialists will be required because everyone who is ill will demand a specialist's opinion, and no general practitioner will dare to open an abscess or treat a severe case of measles, because if anything should go wrong he will be attacked by the officials who supervise him.

Then again, the position in hospitals will change. The number of beds, the number of nurses, technicians, and workers of all types will need considerable expansion, for many more patients will be dealt with and many more forms will be required, as in peacetime Army or Navy medical services. It is proposed that nurses should work a 48-hour week, so that a huge increase in the number of nurses is foreshadowed, and it seems hardly probable that doctors will work longer than 48 hours a week. More than this, the practitioner who in the past has made £800 or £900 a year is to get more, but the able, hard-working, more highly qualified, more successful doctor who may have made as much as £3,500 is to get less, and can anyone be so blind as to fail to see that the incentive to work hard and to do good work is going to be removed. It means that doctors will be less efficient, will not be proud of their profession, will tend to resemble their peacetime counterpart in the Services, do as little medical work as possible, and that poorly. (I will not suggest for a moment that there are not very good men in the Services even in peacetime, but such men rapidly obtain executive positions and early promotion and cease to practise their profession.)

As a learned profession medicine is dead. Whether you like it or not it has been killed by a pink giant, but I am afraid that the practitioner of the future is going to be a poor stick. He will

work a service which is comparable to the telephone service, he will choose neither where to live, what type of practice to engage in, nor whom to work with. He will be selected for special education at the age of 11, he will have the benefit of a free education, he will probably speak B.B.C. English, he will call himself doctor even if he possesses the diploma M.R.C.S., and he will not resemble his predecessors in knowledge, interest in his patients, or capacity. He will work much shorter hours and will retire much sooner, and what his income may be will be of no moment; but medicine as a profession, as an honoured profession, as a learned profession, and as a profession which can offer great help to many friends among the public, is dead.

There is an old Army saying which is worthy of note: "What happens to your patient is of no importance providing your returns are correct."—I am, etc.,

Birmingham.

K. DOUGLAS WILKINSON.

SIR,—Your correspondents, Drs. H. H. Sanguinetti and R. S. V. Marshall (Aug. 10, pp. 206 and 207), complain that the Council does not give a lead to the profession. This feeling is not confined to your two correspondents but seems to be fairly widespread among the general body of practitioners, and until recently has had in my opinion a certain amount of justification.

I feel, however, that the statement by Chairman of Council at the Annual Representative Meeting answers the complaint. It may be argued that this is not so as it does not state what action the Council intends to take *vis-à-vis* the Minister of Health, but what it does do is to put the issues clearly before us. The machinery of a democratic body such as the B.M.A. works from below up, and it is for its members, through their Representatives, to instruct the Council what to do. There is not much good leading until you are assured that those you lead are prepared to follow you. Divisional meetings are often poorly attended, and while the Representative is able to put forward at the Representative Meeting the views of those who do attend, how is he to gauge the views of those who are not there? It is for this reason that the plebiscite is being taken. It is to be remembered also that the whole of our profession (not only the B.M.A., which comprises the large majority) is involved, and that it is the Negotiating Committee and not the Council who will receive and act on our instructions.

One significant statement was made at the Annual Representative Meeting by Chairman of Council. Unfortunately it was not reported in your otherwise excellent and accurate account of the proceedings. Dr. Dain said that he felt it had been a mistake to discuss the question of compensation with the Minister even though it had been clearly stated it was being done "without prejudice." Here, to me at any rate, appears to be the lead for which your correspondents are looking.—I am, etc.,

London, S.E.3.

WM. GUNN.

The Plebiscite

SIR,—Dr. E. D. Broster's letter (Aug. 10, p. 206) is most timely and offers a constructive way in which to approach the problem of the new Health Service. The profession must keep before them the general principle underlying the scheme—the principle of direction, regimentation, and official interference throughout one's professional life.

The scheme should be rejected completely and utterly for one reason and one only—that the whole conception of it is alien to our British ideas of freedom and fair play.—I am, etc.,

London, N.W.10.

R. M. AYTON-ORMISTON.

SIR,—As one of those directly responsible for the motion to have a referendum (as I prefer to call it) I would like to answer Dr. E. D. Broster's letter (Aug. 10, p. 206). The reason why a referendum is necessary soon is that the Council have no longer a mandate to negotiate. They had a mandate to negotiate in the general framework of the Bill to try to get it altered so as to conform with the principles which were considered essential to the freedom of the profession. There were no negotiations; the Minister would not negotiate. There were discussions, but these did not make the Minister amend his Bill in any essential way.

The present position is that the Bill is as good as law, and it contains many things that the majority of the profession apparently do not like. The Minister will shortly proceed to fill in the padding of the Bill, namely the terms and regulations, and

the Council has no mandate to negotiate upon these from the profession. Dr. Broster will find that it was decided that a referendum should be taken soon on the simple issue as to whether there should or should not be negotiations with the Minister on terms and regulations. It is too early yet to ask whether the profession is going to *refuse service*, but a refusal to *negotiate* if carried to its logical conclusion would mean this.—I am, etc.,

Cambridge.

ALEX. BROWN.

SIR,—In his recent statement the Chairman of Council makes it clear that the opinion of all registered medical practitioners will be consulted concerning the question as to whether or not further negotiations should take place with the Minister. I consider that the answer to this question might be misleading. Many practitioners in favour of the new Bill might nevertheless answer in the negative. In view of the Association's attitude to the Bill and its cumbersome statement of irrelevant principles they might desire that the negotiations concerning the working of the new scheme should be left to other bodies.—I am, etc.,

King's Langley.

P. DUPRÉ.

Government Salaried Service

SIR,—The letter of Dr. C. F. C. Parkinson (Aug. 10, p. 208) is extremely apposite. The brief experience of those of us who left the E.M.S. after three months of war to volunteer for one of the Services was enough to impress upon us for all time that the Ministry of Health, as agents of the Treasury in their financial dealings with doctors, are absolutely unscrupulous and capable of even the shabbiest and most petty forms of dishonesty for no better reason than that advisers can apparently be found to assure them that doctors will stand for this kind of treatment.

Dr. Parkinson omits only one detail of this shameful and discreditable story: even during the first three months of the war, while the newly drafted E.M.S. medical officers were still organizing their sector hospitals, a circular reached them from some minor Machiavelli in the Ministry informing them that at the time of their engagement (some six weeks or so before, on the outbreak of war) the Ministry had not appreciated that they were under contract to their parent hospital; and that since the Ministry would not dream of interfering with this 'contract' (which in the case of my own teaching hospital had never existed at all, there being no salary for resident appointments before the war) their later engagement at £350 per annum in the E.M.S. should be considered as cancelled.

The intended effect of this one-sided repudiation of a freely negotiated contract was an economy: the saving of all salaries to junior E.M.S. doctors while their services were retained free by misrepresenting their previous agreement with their own hospital. The effect actually produced was an outburst of incredulous indignation so unexpected and alarming to the Ministry that an immediate retreat was considered expedient. This took the form of a second circular letter naively dismissing the first as an error. But how temporary was this enforced return to straight dealing, how prompt, whole-hearted, and successful was the subsequent official counter-attack designed to evade both spirit and letter of the original contract, can be judged from the facts in Dr. Parkinson's letter.

The moral of this sordid tale is simply that, since doctors are not disposed to strike, they owe it to the public as well as to themselves to ensure that no further opportunities are given to the Ministry of Health to dishonour freely negotiated agreements.—I am, etc.,

Bognor Regis.

D. STAFFORD-CLARK.

Scotland's Health Service

SIR,—Mr. C. W. Key, Parliamentary Secretary to the Ministry of Health, declares: "The powers the Minister has are all powers of a kind which has been enjoyed by Ministers in relation to medical and other benefits under the National Insurance scheme." Yet the principle of the old Act with its sharing of responsibility is not identical with that of the new Act. The people are generally opposed to the original scheme upon at least three grounds: (1) the personal relation between patient and doctor; (2) want of modern scientific benefits—e.g., x rays; (3) official callousness and inexcusable delays.

The drafting of the new Scottish Act should not be carried out either by English or Scottish officials, so long out of vital touch with the clinical problems that matter, but by a special committee of Scottish surgeons and physicians from the four Universities and under the auspices of the Principal of Edinburgh University. This committee would ensure: (1) Free choice of doctor, in or out the scheme. (2) A profession trained by anatomical and surgical experts to operate upon their own patients (not permissible under the English Act). (3) Complete external and internal diagnosis and treatment appropriate to every Scots patient, peasant or millionaire. Extra benefits to the patient to be effectively provided by the officials concerned. (4) Abolition of backstairs and petticoat methods of control. (5) Liberty of the young doctor to buy a house and settle wherever he likes to earn his livelihood. (6) Triennial or quinquennial revisions of the Act.

The chief supporters of central control are from members of the profession who have not handled a clinical case for years. They never realize it is the patient who calls in the doctor, and expects him, like Nelson, to do his duty. He entrusts his life and the lives of his family to a personality. A cogwheel routinist poorly trained and unconcerned except to fill up pretty forms is absolutely no use to the Scots patient. He will expect in the Scottish Act to see some approximation to Sir Hartley Shawcross's dictum: The individual must transcend the State. To secure this, two methods are essential: (1) a return to the individual visit as before 1912; (2) a distinction between Sherlock Holmes the clinician, and Louis Pasteur the administrator. Each must be accorded his proper place in the Scottish National Health Acts of the future, but Louis must serve Sherlock, not control him. The Secretary of State for Scotland has the chance of a lifetime to provide socialism to our people.—I am, etc.

Glasgow.

A. TURNBULL.

Emergency Bed Service

SIR,—The many London doctors who made use of the Service during the war must often have wondered just how long it would continue to work only by day. It was of course always intended that a 24-hour service should be provided, and prior to the war this was done. Wartime difficulties, however, made this impossible to maintain, and for many years the Service has closed at 10 p.m. Indeed, at one time it had to close at "blackout" as the windows and curtains had been blown away.

Now that it is possible to obtain the necessary staff and to run the office free from enemy interference the committee have decided to resume the full 24-hour service, and from 9 a.m. on September 1 it will be available to doctors day and night throughout the year.

The Service continues to deal with all acute and urgent cases, including fevers, but owing to the prevailing shortage of beds in London it often takes considerably longer to find a bed than it did before the war, and it is quite impossible to deal with a case not in absolute need of immediate admission. Subject to these limitations every possible assistance will be given to doctors.—I am, etc.,

London, E.C.2.

R. E. PEERS,
Secretary.

Voluntary Hospitals Emergency Bed Service.

The Outbreak of Smallpox in Middlesex, 1944

SIR,—The report on the outbreak of smallpox in Middlesex in Feb., 1944, by Drs. W. H. Bradley, J. O. F. Davies, and J. A. Durante (Aug. 10, p. 194), is very welcome even though a little belated. It affords a striking illustration of the efficacy of modern methods of dealing with an outbreak of highly virulent smallpox, even when the circumstances appear to be highly favourable for spread, without recourse to mass vaccination of the general population. Much credit is due to the medical authorities who dealt with the outbreak so efficiently and successfully. One only wishes the report could have been made public earlier so that it could have been an encouragement to other authorities, where somewhat similar outbreaks have occurred, to refrain from rushing into mass-vaccination campaigns with all the attendant risks to life and health which such campaigns inevitably entail.

There are certain aspects of the outbreak as detailed in the report which deserve stressing:

(1) The initial case, the cause of the outbreak, was a soldier

arriving from Gibraltar. He had been well vaccinated in infancy and successfully revaccinated in Sept., 1942, i.e., less than eight months previously. The attack, as we should expect, was highly modified, and the case was diagnosed as chicken-pox. We are told if the case was seen by any doctor with previous experience of smallpox, but in view of the serious consequences likely to follow any mistake in diagnosis it certainly seems desirable that any case presenting symptoms which might possibly be smallpox, especially in soldiers returning from the East, should be referred to an expert or, if this is not feasible, should at least be isolated effectively. In this case we are told that the patient was allowed to be up and about, visited other parts of the hospital, and had his hair cut by a barber in company with a number of other patients.

(2) The failure of successful revaccination to protect completely for even eighteen months is certainly surprising and rather disconcerting. It illustrates the limitations of vaccination and affords a warning against over-confidence in its efficacy.

(3) Four out of the eleven cases in the outbreak occurred in nurses, and one of these, who had never been vaccinated, died. The other three had not been vaccinated since childhood. This certainly suggests that all nurses, like all doctors, ought to be protected as far as possible by repeated vaccinations. Case 11 makes the same observation applicable to ambulance drivers.

(4) At the same time it is noteworthy that among those members of the nursing staff who had never been vaccinated there were several who did not contract the disease although they were brought close in contact with it. This supports the view that smallpox does not "pick out" the unvaccinated to the extent that used to be taught at one time.

(5) In spite of the failure of comparatively recent vaccination to protect the initial case the outbreak affords evidence of the power of vaccination, even though performed in infancy many years before to modify an attack and make it milder.

(6) The outbreak also supports the contention that vaccination, even though only performed in the incubation period, does diminish the severity of an attack.

Admittedly, the number of cases dealt with in the outbreak was too small to justify any very dogmatic assumptions.—I am, etc.,

Leicester.

C. KILLICK MILLARD.

Socialism and the Pay-bed

SIR,—I have read the letters of Mr. H. I. Deitch (July 1, p. 139) and of others on this subject and agree entirely with many points they raised. I should be the last to suggest that any person who needs a private ward should not have one; I doubt this will one day be possible on medical grounds. At the same time I do not see why those who wish to pay for such wards should have to submit to interference with the use of their money. To attempt such interference smacks of National Socialism on the German model.

I do not understand how Mr. Deitch is able to exclude a sick person from hospital however excellent his reasons. As far as I know all sick poor may demand hospital care if they wish. The measures he took seem to be admirable, but not the superintendents are as resolute in defending their staffs as the other patients from contact with objectionable people. It is unfortunately true that in some places local politics colour these matters quite a lot. Many doctors, and even schoolmasters, will say that it is professionally advantageous to have politics of the colour to please one's employers. This is dangerous, as we have countless examples in the shape of revolutionary France, Nazi Germany, Communist Russia, and so on. In each and every case the mixing of politics with professional or technical activities has proved harmful and productive of inefficiency.

I did not suggest, and I do not believe, that sensitive and refined people are only found in one class. I have been a patient in private and public wards and do not mind either provided that obnoxious behaviour can be immediately checked without fear of any political repercussions.—I am, etc.,

Colchester.

G. C. PETHER.

SIR,—If your correspondent, Dr. Ian C. Gilliland (Aug. 1, p. 211), could know the chorus of approval reaching me from far and near which has greeted my original letter (June 2, p. 968) on this subject he would be even more "surprised." I shall not myself answer his questions about the definition of desirable genes and their transmissibility. If he sincerely wishes information on these subjects there are numerous works of accredited authors which will supply his need much more fully than would be possible in a short letter. The following may

Tetanus Antitoxin

Clinical and experimental observations have proved the value of tetanus antitoxin when used prophylactically. A dose of 3,000 to 6,000 international units should, therefore, be administered in all cases where there is a possibility of infection with *B. tetani*. If an operation is considered necessary the antitoxin should be given 3 to 6 hours before any attempt is made to clean the wound.

If any manifestations of tetanus are observed, energetic specific treatment should be commenced immediately. A dose of 32,000 or 40,000 international units should be injected intrathecally, and the same or an even greater amount should be given intramuscularly. Further doses depend upon the patient's condition, and when this improves the amount of antitoxin administered may be gradually diminished.

Concentrated Tetanus Antitoxin:

HYPERTENSION

—AN ANALOGY

The safety-valve emitting steam warns of excessive pressure. The hypertensive patient who "lets off steam" also gives a danger-signal.

"Damping-down" will prevent the crisis in man as in the machine. The aim must be to improve the subjective condition of the patient by reducing vascular and nervous tension and by promoting mental and physical comfort.

A combination of theobromine, to produce peripheral vasodilation, and 'Luminal,' to allay nervous irritability, has proved useful for this purpose.

TRADE **Theominal** MARK

'Theominal,' brand of theobromine & 'Luminal,' is made in England and supplied in tablets, containing gr. 5 theobromine and gr. 1 'Luminal,' in bottles of 20, 50, 100 and 1000.
(* 'Luminal' is a trade mark, brand of phenobarbitone)

TRADE MARK **'SECONAL SODIUM'** BRAND

SODIUM PROPYL-METHYL-CARBINYL
ALLYL BARBITURATE
(Formerly known as 'Seconal')

For generations certain elements of medical research have been directed towards the safety of childbirth and the general improvement of obstetric practice. Careful employment of a barbiturate often mitigates the bitterness of labour and helps to bring the mother through with little recollection of her ordeal.

Developed in the Lilly Research Laboratories, 'Seconal Sodium' is a barbiturate with prompt but comparatively brief effect. Short-acting 'Seconal Sodium' permits better control of hypnosis than when longer acting barbiturates are administered and is relatively non-toxic within the latitude of therapeutic requirements.

THE INTRA VAGINAL TAMPON

*in Menstrual Hygiene
minimizes the risk of infection*

THE correct position of the internal tampon avoids contact with both anal and urethral sources of contamination. Tampax tampons are simply and hygienically inserted in correct proximity to the cervix by means of a disposable 'applicator' tube, only $\frac{1}{8}$ " in diameter. The function of the applicator in inserting the tampon at the upper end of the vaginal tract is of the greatest importance. It eliminates any handling of the highly-compressed soft surgical cotton, and ensures comfort and steady absorption. Tampax tampons are easily removed and disposed of, by means of a moisture-proof cord 'built into' the tampon in its first stage of manufacture, proof also against any risk of disintegration. The positive 'wick' action of the surgical cotton obviates any blocking of the flow.

Tampax may confidently be recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymenal aperture would cause difficulty in insertion and withdrawal.

CHLOROFORM

SIR JAMES YOUNG SIMPSON

OUR association with the manufacture of Chloroform dates back to 1847, when Sir James Young Simpson demonstrated its anaesthetic properties and approached Dr. Thomas Smith (Founder of our Firm) with a view to obtaining sufficient quantities to carry out his pioneer work.

Our long experience enables us to produce an anaesthetic chloroform of standard composition, UNSURPASSED FOR RELIABILITY, and answering the tests of all pharmacopoeias.

AND AT
LONDON &
GLASGOW

recommended: *Applied Eugenics*, Popenoe and Johnson (Macmillan); *World Population*, Carr-Saunders (Oxford); *Introduction to Human Genetics*, Fraser Roberts (Oxford Medical Publications).

However, I must in self-defence point out that he has craftily transferred the word "acquired" from paragraph 2 of my letter to the last paragraph, thereby making it appear that he has suggested that acquired characters are transmissible—a most evident pitfall which even I should know how to circumvent. On this subject too there is a voluminous and easily available literature. Prof. Arthur Thomson's book *Heredity* contains an admirable summing up of the evidence for and against such transmissibility.

Again, Dr. Gilliland writes: "The contention of the whole medical officers of the Middlesex County Council is that privacy should be obtainable on medical grounds." Nobody could question this, but this was not the contention of these medical officers. Their contention was that "patients should receive extra privacy, etc., solely on medical grounds." The word "solely" has been conveniently omitted. It is the essence of the question. A sound case would not require bolstering up by such tricks.

This correspondence is degenerating to the plane of personalities and obloquy, and that is not owing to any disagreement on the subject of genetics, which, though a comparatively new science, is sufficiently established for our present elementary needs. The anger of my critics is aroused because I have dared to touch with hands irreverent the socialist shrine, which of course I should have known to be sacrosanct. Let me therefore in an attempt to retrieve the discussion from mud-slinging briefly reaffirm the basic principle for which my first letter was written. This principle, the premise from which all legislation would in my opinion do well to start, is the effect of such legislation on the quality of future human stocks. The discovery, preservation, encouragement, and propagation of our best stocks, wherever found, without reference to financial or social status—that "real aristocracy of natural intellectual endowment, character, rectitude, social desirability, and service not the class usually referred to as aristocrats, who may or may not be desirable eugenic types"—is surely an objective in which all political parties could unite. Such enlightened policy would be of inestimable service to society in the near future and in remote generations would be capable of producing in the race a quality undreamed of by the many. Moreover, the higher the general standard of the population the more likely is it to produce those exceptional variants on whom the direction and advancement of the community so largely revolves. It is almost certain that the human faculties have not reached anything approaching their highest expression and greatest development, even with such outstanding men as Shakespeare, Isaac Newton, Darwin, Einstein, etc. It is also certain that many factors—e.g., misguided political adventures not confined to any one party—perpetually weigh the scales in the opposite direction. Of this dysgenic action numerous examples will occur to everybody, but among them (in order to avoid home politics) may be instanced the elimination and destruction of intellectuals by the Germans in the over-run countries, a similar process in the early days of the Soviet Union, and of course war itself. Legislation leading to betterment of humanity is good, and legislation leading to deterioration is bad.

If these simple truths and ideals could be grasped by politicians, and better still by the community, would it be too much to hope that a complete re-orientation of political objectives might result? It is to a consideration of these facts that one would presume to invite the profession in order to urge their leadership in this biological matter so easily grasped by ourselves, so little understood by the general public. Unless they do so the serious danger of racial deterioration faces us.

And where does "Socialism and the Pay-bed" come in for reference to all this? Simply that the proposed rules for the use of the pay-bed constitute just one of many political pin-pricks, some large, some small, militating against the interests of the better eugenic types which I have previously defined and leading to their discouragement. (On the differential birth rate much has been written. The Galton lecture by Mr. C. J. Bond can be read with profit and a précis is printed in the *Journal*, 1928, 1, 315.) Though my critic complains that the

connexion between the two is not evident it will be clear to the majority, and a little unbiased reflection should clarify it for him also. To the above attitude the terms "snobbishness" and "bigoted" seem singularly inappropriate. Concerning itself solely with the interests of future generations it appears completely altruistic and unselfish and is indeed the truest form of service to the community, far transcending that doctrinaire socialism which is admittedly devoted to the narrow interests of a single class and which as at present practised is, I repeat, dysgenic and antisocial in many of its aspects.—I am, etc.,

Grasmere

JAS. B. MACALPINE.

*This correspondence is now closed.—ED., *B.M.J.*

Nutrition of Far Eastern Internees

SIR,—I think I can assure Dr. C. Romer (Aug. 3, p. 176) that nocturnal diuresis among Far East internees was not due to any specific factor in rice. In the summer of 1940 at an officers' camp in Germany the same phenomenon was noticeable, beginning immediately after arrival at a permanent camp following a rather tiring march of two weeks on very poor rations, and continuing in most cases until the arrival of Red Cross parcels and a consequent increase in protein intake. In this case the diuresis was attributed by the P.O.W.s variously to the potatoes or the watery vegetable soup, which, with bread, constituted most of the diet; while I do not think that rice was ever included. Stools also were very bulky.

In referring to a low protein intake it is perhaps worth noting that in the first six weeks of this poor diet there were three clinical cases of acute attacks of gout (in each case in men who had previously had gout) to the intense indignation of the victims, who felt that it was an unfair imposition in the circumstances. It is only fair to add that Bavarian beer was available.—I am, etc.,

Hereford.

A. F. STALLARD.

Shock Treatment of Bronchial Asthma

SIR,—I am in complete agreement with Dr. E. M. Fraenkel's remarks (Aug. 3, p. 174) on the shock treatment of bronchial asthma. I have paid particular attention to the treatment of this condition for some considerable time and I have come to the conclusion that it is one of the diseases which demands individual attention and analysis more, perhaps, than any other and that it is most inadvisable to dogmatize on the merits of any particular form of treatment. It has been my experience that a method of treatment which might give very satisfactory results in one patient might prove equally disappointing in another.—I am, etc.,

London, W.1.

E. S. FENNELL.

Reiter's Disease

SIR,—I have read with interest the article on Reiter's disease by Flight-Lieut. W. P. U. Jackson (Aug. 10, p. 197). While in charge of cases of bacillary dysentery in the Middle East I encountered a combination of polyarthritis, urethritis, and conjunctivitis more than once in patients admitted with acute diarrhoea and showing a bacillary exudate on microscopical examination of their stools. As severe diarrhoea is apparently a feature of Reiter's disease it must be difficult at times to distinguish this from bacillary dysentery complicated by the same triad of symptoms.—I am, etc.,

Grays, Essex.

R. N. HERSON.

SIR,—In the *Journal* of Aug. 10 (pp. 197 and 199) are two notes on Reiter's disease by Flight-Lieut. W. P. U. Jackson and Dr. F. Wrigley. These authors state that the aetiology of this disease is unknown.

Actually there is a very similar syndrome—characterized by conjunctivitis or iritis, arthritis, and urethritis, often associated with colitis (although the colitis may be absent)—which constitutes a well-known but uncommon sequel to bacillary dysentery, generally of the Shiga or Flexner type. This post-dysenteric syndrome may begin two or three months after an attack of dysentery.

In my experience a Service patient was sent to the laboratory for examination of the discharge from his urethra. We observed

that he had conjunctivitis, so this discharge was examined also. Both results were negative so far as venereal disease was concerned. The patient later developed arthritis. Much later his history was inquired into. Then it was found that he had been discharged "cured" from a hospital after being an in-patient with an attack of "dysentery" some three months previous to visiting us with the urethral discharge.

It is easy to miss pertinent items of medical history when the patient presents himself (or herself) with symptoms that have a steep venereal "slant."—I am, etc.,

Epping.

FRANK MARSH.

Ligature of the Cord

SIR,—There appeared in your columns a few months ago a number of letters on ligature of the cord. Your correspondents emphasized the necessity for double ligature. It is interesting, therefore, to note what may happen when the parturient woman ignores all the complicated modern machinery of antenatal and natal care and leaves it all to Nature. At one time or another most practitioners will have been called to a woman in labour where pregnancy has been concealed and where no preparations of any kind have been made, and has perforce to be midwife as well as accoucheur. Few, however, can have had the experience of such detachment as I have found in one family in my practice.

About 6 a.m. on Feb. 13, 1943, I was called to the house of P. X., a legless ex-soldier, who with his aged and bedridden wife occupied the ground floor only of his house. The upstairs rooms, unused and uncare-for for years, were thick with undisturbed dust and dirt. In the midst of all this his grand-daughter A. X., an unmarried girl of 20, had delivered herself of a fine boy some hours before. The placenta had been expelled and the cord had been torn across about 2 in. (5 cm.) from the umbilicus, and no ligature had been applied. There was no bleeding and the baby was vigorous and showed no sign of past loss of blood. The perineum was intact. No preparations of any kind had been made. Mother and baby were sent into hospital and the puerperium was uneventful.

On Oct. 8, 1944, I was called to the house of T. X., father of the last case (A. X.). His newly married second wife, G. X., had given birth to a daughter. The baby was vigorous. In this case, though the placenta had been expelled, the cord had not been tied. No preparations of any kind had been made, and both mother and child were sent to hospital, where the puerperium was uneventful.

On April 8, 1946, Mrs. K. Y., a married daughter of T. X., was delivered under exactly the same conditions. Her husband knocked up my assistant, requesting an ambulance to take her to hospital.

On April 15, 1946, at 6.40 a.m., I was again called to A. X., who was reported to have a retained placenta. She had delivered herself unattended about 11 p.m. the previous night and had divided and tied the cord with tape. Even the placenta had been expelled when I arrived. There was a good contraction, and no evidence of haemorrhage. Again there were no preparations, and mother and baby were sent to hospital.

It is difficult to understand why these three women should flaunt accepted practice and braved my, by no means needless, horror and indignation. They should have suffered from toxæmia of pregnancy, disproportion, malposition, obstructed labour, torn perineum, puerperal haemorrhage, puerperal sepsis, and possibly a number of other unpleasant complications. The infants should have been asphyxiated or died from haemorrhage from the cord. Orthodox obstetricians will understand how disappointed I felt to find that there was not even a minute tear of the perineum.—I am, etc.,

Preston.

F. M. ROSE.

The "Intractable" Vesico-vaginal Fistula

SIR,—Surely Drs. O. S. Heyns and P. Keen (July 20, p. 99) are reading more in Prof. Chassar Moir's letter (May 18, 1946) than he actually wrote? He deplored undue pessimism and unnecessary resort to transplantation of ureters, and both writers agree with him. But it is surely unjustifiable to assume that because Prof. Moir has had 100% success in repair by the vaginal route he therefore believes that all cases can be cured so. I am unable to read any such suggestion into his letter.

If figures are to be quoted, however, let us remember that percentages are misleading in small series and that "difficulty" is as hard to assess as pain. While difficulty may vary from country to country it is probable that in a series of thirty or more unselected cases in any one country the difficulties would be comparable with other such series in the same country.

The larger the series the more likely are the cases to be selected though not by the surgeon himself but by his friends who send him their problems. How cases may on the average vary from country to country there must be few surgeons who say. I have felt that most of my cases, all seen in Madras, were very difficult, but I am unable to say how they compare with those in the Bantu. I feel that sufficient information rarely offered when series of cases are presented. Th. Dr. Keen has transplanted eight cases in ten years, and Muri (1943), has transplanted some sixty cases over a number of years. But what we need to know is what percentages are of all the cases seen? Again, Dr. Heyns has transplanted "some cases of fistula," but where repair *per vaginam* has been impossible, so, frequently, has transplantation as well. Where transplantation has been possible repair *per vaginam* could be effected "without difficulty." Thus he finds that with inoperable fistula transplantation is very often impossible to. But when does he regard a fistula as inoperable? I regard them as inoperable when about half the lower border of the fistula consists of the periosteum of the pubis. I have hitherto needed to do only six transplantations, and none was difficult. But these were not the cases which had the most scarring of the vagina (and presumably the most adhesions in the pelvis) they were the cases where the fistula happened to be low and bounded by bone, and without urethras. High fistulae, with dense scarring in the vagina, no recognizable cervix, and quite immobile—and far more likely to have had pelvic peritonitis—were all repaired from below.

I think it is sufficiently obvious that we are talking to some extent at cross purposes, and I therefore suggest that we present our figures on a definite plan. This will clear up what difficulties can be cleared up, and as for assessing degrees of difficulty we must be content to wait until we can see cases in other countries. It is no great matter if one surgeon has 5% more cures than another; what does matter is that difficulties in understanding one another should be reduced as far as possible.

Dr. Heyns makes the point that loss of vaginal tissue and the urethra are the complications which militated most against success. I have elsewhere (Thomas, 1945) classified fistulae: juxta-cervical, mid-vaginal, or juxta-urethral, and shown that the high juxta-cervical fistulae and the mid-vaginal are more easily repaired than the low juxta-urethral, although they may be extremely difficult. The following suggestions are made with this point in mind, and are illustrated by figures from my own series.

The total numbers of fistulae seen, excluding those due to cancer and lymphogranuloma, may be set out as follows:

TABLE I

	J.C.	M.V.	J.U.	Total
Cases seen	22	6	30	58
Obstetric	21	6	30	57
Radium burn	1	—	—	1
Surgical trauma	—	—	—	—
Totals	22	6	30	58
Refused treatment	1	—	3	4
Submitted to treatment	21	6	27	54
Repaired by vaginal route	20	6	17	43
Failures	1	—	10	11

TABLE II.—Analysis of Failures

J.C. Pulled out her catheter, and had residual pin-point fistula, but did not return	1
J.U. Refused second operation	1
Refused transplantation of second ureter after successful first stage	1
Refused any transplantation	1
Successful double transplantation	3
Death from transplantation	2
Successful colpocelesis	1
Complete failure (inoperable V.V.F.) and failed R.V.F.	1
	11

1. To arrive at percentages (and one must admit they have much the same attraction as have those of Wisden, and perhaps about the same practical value) we must in assessing the "cure rate" neglect patients who refuse a second operation when they might well have been cured by one, and of course those who refuse treatment at all. Of 54 cases, one refused a second vaginal operation, and another (the J.C. case) failed to return. Thus of 52 cases 43 were repaired: 82%.

2. To assess the "total relief rate" we must add to the repairs

ose relieved by transplantation or colpocleisis. The cases refusing liefl operations should not be included. Thus, of 54 cases, 4 refused ther a second vaginal operation, or a relief operation, leaving 50 ses. Of these, 43 were repaired, 3 underwent successful trans- lantation, and 1 colpocleisis, giving a total of 47 cured or relieved, 94%.

3. Percentage of cases relieved only, out of the total of those ilicved and cured:

$$\frac{\text{cases only relieved} \times 100}{\text{cases cured and relieved}} = \frac{4 \times 100}{47} = 8.5\%$$

4. Cases complicated by the presence of other fistulae should be rded as it may give some idea of the severity of the condition. hree cases had an associated uretero-vaginal fistula: in each the V.V.F. was repaired; in one a nephrectomy was necessary; and n the other two the offending ureter was transplanted into the igmoid. The three cases were complicated by a recto-vaginal fistula: ne had both fistulae repaired, another had the R.V.F. repaired, and oth ureters transplanted (V.V.F. inoperable), and the third had n inoperable V.V.F. in which several attempts to cure the R.V.F. alled.

5. One's criterion of inoperability and how many the series ncluded (3 cases).

6. Number of cases treated previously operated upon elsewhere nd how often: 11—9 once, 1 twice, and 1 four times. These include wo of my failures and nine repairs:

7. Successful cases which required more than one attempt: one in his series had two vaginal operations; all the other successes bealing it my first attempt.

Would not records on these lines do much to enable workers to avoid avoidable misunderstanding? It is doubtful if further information could usefully be offered, short of supplying full case notes.—I am, etc.,

Bournemouth.

Lice in Hospital

SIR,—After six years spent with a relatively non-verminous military population it is depressing to realize that one's own people can be indifferent to the louse. This realization focused attention on the prevalence of lice, and the noting of verminous patients on admission to hospital during the past two years makes it possible to deal with true figures. Patients examined have all suffered from notifiable disease and may be considered a fair cross-section of the Lanarkshire population, since all grades of society find themselves at times in an isolation hospital. No distinction was drawn between head and body lice, since it is reasonable to regard these as the same insect. Nits have been taken as evidence of lousiness.

Tabulation of the available figures show:

TABLE A.—Gross Figures: Louse Infestation

Year	Total Admissions	Verminous	Clean	% Verminous
1944	1,983	566	1,417	29%
1945	1,895	670	1,225	35%
1946 (Jan. and Feb.) ..	394	119	275	30%
Total	4,272	1,355	2,917	32%

It would appear that approximately 1 in 3 of the patients admitted were lousy on leaving their homes.

TABLE B.—Age and Sex Incidence (1944, 1945, 1946, Jan. and Feb.)

Sex	Age Group	Verminous	Clean	% Verminous
Males	0-4.9	130	413	24%
	5-13.9	253	559	31%
	14-17.9	22	104	18%
	18+	21	529	4%
Females	0-4.9	142	303	32%
	5-13.9	494	375	57%
	14-17.9	63	54	54%
	18+	230	580	28%
Total		1,355	2,917	32%

The relatively high incidence in children of both sexes in the pre-school age group suggests neglect on the part of parents, and the incidence among adult women indicates a lack of personal cleanliness which cannot but be reflected on their children. The female figures are all bad, and it is depressing

to note the condition of school-age children (males 31%, females 57%). These figures seem to demonstrate a certain futility in the present methods of eradicating lice in schools. They indicate, too, the chance a clean child has of acquiring lice. Lousiness among adolescent girls at as high a rate as 54% is an ill augury for the mothers of the future. The reasonable figures for adult males cannot be due to lack of available infection, but undoubtedly short cropping of male hair creates an uncomfortable environment for the louse just as the apparently untouchable and unwashable "perm" provides a secure retreat. When the problem is considered honestly there is no real reason why anybody in this country should harbour lice, and it seems apparent that apathy, indifference, and laziness are the real reasons why British lice still flourish.

In the County Hospital, Motherwell, dichlorodiphenyltrichloroethane (D.D.T.) as a 5% dust in talc has been used to control these vermin. A simple dusting with the powder on admission suffices to kill the lice, and as nits hatch out the still effective powder destroys the nymphs. No toxic effects have been observed, and in these days of nursing shortage D.D.T. saves much time and obviates embarrassing scenes with female patients. The good uses of D.D.T. have been seen on a large scale abroad, and there seems no reason why the 5% dust, applied perhaps once a month to school-children, should not reduce the present verminous condition to infinitesimal proportions. D.D.T., being stable and effective for several weeks, should take care of renewed infestation in the home. In schools the dust could be applied rapidly, economically, and without offence, by the use of a dust-gun.—I am, etc.,

Weston-super-Mare.

JAMES MACRAE.

Rheumatic Fever

SIR,—When Dr. H. S. Barber reads Dr. K. Douglas Wilkinson's letter (Aug. 3, p. 174) I hope he will not feel too crushed and discouraged. Nearly 20 years ago, when I was doing some work on allergy, the late Dr. Oriel, whose work on the biochemical aspect of allergy was well known, told me that he had evidence which convinced him that the articular symptoms of acute rheumatism were an allergic response.

Dr. Wilkinson wants Dr. Barber to explain the response of acute rheumatism to the salicylates. Asthma, which I prefer to regard as a syndrome rather than a disease, is distinguished chiefly by bronchospasm. There are various causes of bronchospasm, and I and many others have observed the response of the allergic variety to acetyl-salicylic acid. Some patients have even made the discovery for themselves.

I have no doubt that Dr. Barber will probably answer Dr. Wilkinson in detail.—I am, etc.,

Brookwood.

H. M. STANLEY TURNER.

Achromotrichia in Tropical Malnutrition

SIR,—I was interested in Dr. William Hughes's article on achromotrichia in African children (July 20, p. 85) as I have recently seen similar types of depigmentation of hair and skin in Europe. I should explain that I am an Army M.O. with administrative charge of a Civilian Internment Camp. The internees are here pending investigation of their part in the Nazi régime, etc. Many of them are considerably undernourished, and recently I have seen four cases with the following points of similarity:

(1) All were males over 55 years of age and had been in a poor state of nourishment previous to arrest.

(2) On the backs of the hands, the wrists, and front of the neck the skin was thickened, brown, and there was a flaky desquamation. Two of the men showed snow-white patches in these brown areas.

(3) The tongue was rather red and quite smooth. There was no pain or burning taste.

I wondered if this might be a pre-pellagra stage, although there were no signs of C.N.S. involvement or diarrhoea, etc. Large doses of vitamin B₃ and increased diet had no effect. Unfortunately vitamin B₃ is not available.

I have noticed several cases of depigmentation of a patchy type in the hair. It cannot be pulled out painlessly though. The German doctors here consider this to be a symptom of anxiety rather than malnutrition.—I am, etc.,

Pleural Shock or Cerebral Air Embolism

SIR,—It is true that when a clinician describes a patient as being in a state of "shock" he is not diagnosing a specific disease but is employing a convenient label to attach to a clinical syndrome—i.e., to a fairly clearly defined group of symptoms and signs. Unfortunately it is true to say that the diagnosis of "shock" in general is so loosely and variously employed that it may fail to give an outsider an exact indication of how ill the patient is, or of what symptoms and signs he would display to the bedside observer, or of what treatment he would require. I quite agree, however, that it is rather difficult to differentiate between "pleural shock" and "air embolism" (July 20, p. 94) during a thoracic manipulation on seeing these conditions for the first time. Once seen, however, one realizes that one may be dealing with one of two complete and separate conditions.

Needless to say that air embolism may arise as a complication of pleural puncture, but it is hardly possible that so-called "pleural shock" is always due to air embolism and not to a pleural reflex. Air embolism sometimes resembles pleural shock in its manifestation, but it is quite different in its origin. It results from the entry of air into the pulmonary veins and its passage as emboli to the coronary or the cerebral arteries. Death may be immediate, or there may be epileptiform fits, hemiplegia, or profound unconsciousness. In rare cases it may be survived. Air embolism should be extremely unusual if it is always ascertained that the pneumothorax needle is within the pleural cavity by the characteristic oscillation in the manometer.

As I have had the opportunity to make observations upon such cases I would venture to submit these three accounts and the following comments as having bearing upon your annotation in the hope that they may prove of interest in particular to those clinicians who do not accept the difference between the two conditions. The following are the descriptions of the cases: on each occasion I happened to be an eyewitness to the attacks.

Case No. 1.—This occurred in a middle-aged man who was admitted to the hospital with chronic bronchitis, emphysema, and fibrosis of the lung. He constantly complained of severe pain in left side of chest, not responding to medical treatment. To relieve the pain a small artificial pneumothorax was performed at the site of maximal intensity. As soon as a few ml. of air had been introduced into the pleural cavity the patient's pulse slowed down markedly; the blood-pressure fell to 90/70; he became restless, extremely dyspnoic, and he died within a few minutes, apparently from syncope. Necropsy did not reveal any air entry into the circulatory system.

But "pleural shock" as a reflex phenomenon can be better demonstrated by the following two reports:

Case No. 2.—A young man of 28 suffering from severe emphysema had developed a spontaneous pneumothorax. The symptoms were very dramatic: sudden pain in the affected side, very severe cyanosis, and cyanosis (i.e., cardio-respiratory embarrassment) were the main features. The physical signs coupled with the radiological findings showed a large spontaneous pneumothorax from a ruptured bulla. During the attempted withdrawal of air from the pleural cavity to mitigate cardio-respiratory embarrassment signs of severe syncope appeared, together with slow pulse, fall of blood pressure, and cold sweating. The aspiration had to be abandoned.

Case No. 3.—A female patient aged 45 was admitted to hospital for investigation and observation of her lung condition, which proved to be an abscess in the upper part of the left lower lobe. Three days after admission she was suddenly seized with an excruciating pain in the left side of the chest in the precordial region. She developed severe cyanosis, cough, and dyspnoea. The pulse became rapid, and she lay motionless, suffering from great pain. The breathing became shallow and frequent. Only later, about three hours after the attack, did physical investigation reveal a large pleural effusion as a result of rupture of the abscess into the pleural cavity. X-ray examination showed an air- and fluid-level, and aspiration yielded pus. Following the first aspiration the patient immediately collapsed, the pulse became slow, and the blood pressure fell to 80/60.

All three cases are characteristic in their uniform reaction, course, and symptomatology, with the exception of the first one, who succumbed, whereas in the two latter ones recovery was immediate after discontinuation of the procedure. Although the cases discussed were not always associated with artificial introduction of air into the pleural cavity, analogy can and should be drawn in order to explain syndromes arising during

damage to the pleura, characterized with marked slowing of the pulse, pallor, faintness, and, above all, profound fall of blood pressure, which may occasionally lead to a fatal syncope.

Pleural shock.—The cardio-vascular reaction is apparent due to a pleural reflex, since a similar effect upon the heart rate and blood pressure can be induced in animals by stimulating the pleura. It is more commonly seen as mentioned above when the chest is punctured for the withdrawal of fluid or rather than during the induction of air in the production of pneumothorax, a fact among others which argues against its being due to air embolism. Injury to the visceral pleura or the underlying layer of pulmonary tissue appears to be a factor essential for the production of this type of circulatory collapse. This may also explain "pulmonary shock" as a common occurrence when spontaneous pneumothorax occurs in the course of treatment by artificial pneumothorax—i.e., rupture of the lung tissue owing to increasing tension upon adhesions. I noticed also that the reactions occurred chiefly in nervous patients and if the pleura is not anaesthetized.

If the descriptions and suggestions just made are taken into consideration immediate "pleural shock" would turn out to be closely related to the reflex vaso-vagal syndrome, or fainting attacks, associated with slowing of the heart and peripheral vasodilatation and fall of blood pressure, with a result of syncope and, very rarely, death.—I am, etc.,

Hitchin.

D. GUTMANN.

Clinical Pathology and General Practice

SIR,—All are agreed (Dr. S. C. Dyke, July 20, p. 95) that family doctors need facilities for simple laboratory tests. How are they to be provided? First, it is utterly useless to suggest that teaching hospitals or universities shall do this work. They are already understaffed and overworked. Their loads must be reduced so that they may undertake relatively more teaching and original investigations.

Possible methods are: (1) That the Association of Clinical Pathologists organize a service to cover the whole country. Much of the private consulting work is already undertaken by members of this Association, which, however, is not big enough yet to tackle the whole population. (2) That family doctors themselves be trained to do much of the work. Personally, I regard this as the best solution, but clearly each doctor would be able to deal with fewer patients, and the nation would need more doctors. (3) That practitioners' own dispensers be trained in clinical laboratory methods. (4) That the Pharmaceutical Society organize a clinical pathological service to cover the whole country. (5) That trained laboratory technicians do the work for practitioners or groups of practitioners. The difficulties of this arrangement are to guarantee a livelihood for technicians and to see that a good standard of work is maintained in relative isolation. (6) A combination of (1) and (4). (7) If the National Health Service materializes, that family doctors refer their clinical pathology to the pathological departments in their local Health Centres. The great advantage of this would be ease of consultation between practitioner and pathologist. The great danger would be that in time Health Centres would be flooded with routine work and practitioners might become less self-reliant.

In writing these notes I have not forgotten the excellent work done by the E.M.S. Pathological Service.—I am, etc.,

Chelmsfield.

G. A. HARRISON.

Nomenclature of Chemical Compounds

SIR,—I would like to draw attention to the frequency with which an element is blamed for the toxicity of one of its compounds through lax nomenclature. For instance, poisoning by any of the compounds of mercury is often referred to as mercurial poisoning. Similarly, but less frequently, this applies to the compounds of lead, arsenic, chromium, and other elements.

This may seem a small point, but I believe it is very misleading and often causes false impressions. I have heard surprise expressed that mercury fulminate or mercury bichloride or calomel did not cause the classic symptoms of stomatitis, tremor, and erethism; but the surprise should rather be if similar symptoms were produced, for it is almost the same as expecting chlorine poisoning from common salt.

There are always exceptions. Some substances are easily broken down or are acted upon in the body so as to cause symptoms related to their components; whilst others, apparently by coincidence, may have similarity of action. In the vast majority should be treated as separate entities, the slightest change in structure being likely to cause profound differences in their reaction. This is well illustrated by some of the organic compounds in which even an isomeric change may mean the difference between life and death. May I therefore offer my plea: chemical names in full when referring to toxic compounds.—I am, etc.,

London, S.E.18.

A. L. LEIGH SILVER.

Psychology in the Child's Education

SIR,—What a shame that Dr. Ellis Stungo should be accused of supporting Nazism as a result of his letter (June 15, p. 930). I am sure that in discussing the Educational, Scientific, and Cultural Organization of U.N.O. he is much more imbued by the spirit of Sir Galahad than by that of Adolf Hitler, and if the holy grail does not after all consist of the simple manoeuvre of teaching psychology in the classroom, nevertheless he has emphasized the fact that education is failing in many quarters to justify its literal translation of "leading out" in us a knowledge of ourselves. I agree with the criticism that the teaching of psychology directly to children is as likely to create introversion as it is likely to "educate." No expert psychiatrist would present his patient with the facts of his neurosis face to face. He "leads out" the patient's insight and allows him to educate himself gradually—so with the teacher and the pupil. Literature teaches children psychology: the Brontës, Shakespeare, Barrie were all good teachers of psychology; and, as Dr. Stungo says, religious instruction teaches psychology.

I think the variety of opinions expressed in this correspondence should emphasize that psychiatrists as a group should be the last people to teach anyone. We can give information; we can educate our neurotics along the lines of psycho-analysis; but our banner carries the motto "*Quot homines tot sententiae*."

We can do a lot of good in providing the teachers with the information they want to know, subject to their own discretion, and there is no lack of desire for that. The four child guidance clinics of which I have the honour to be in charge deal with the teachers of a county, a county borough, and part of another county in the vicinity of London, and I find that the teachers are not only well informed psychologically but are keen for more psychiatric information and direction in the disposal of their abnormal pupils. In Glasgow, I understand, there is an extensively organized relationship between chosen teachers who visit the corporation clinics and the child psychiatrists.—I am, etc.,

Kingston-on-Thames.

JOHN A. McCLUSKIE.

SIR,—The recent letters on the above important subject are of interest, but we must realize in spite of one of the letters that there is a yawning gulf between this subject and that of planning the world's future. There is no doubt that psychology must play its part, important but limited in extent; but just as Dr. Ellis Stungo suggests that there must be a careful selection of teachers—and no doubt many other admirable leaders—so also he should be the first to admit that there must be a careful selection of psychiatrists. If one is going to psycho-analyse every action and word of every child and adult with regard to the past, present, and future, then we shall never have the time even to psycho-analyse the numerous daily actions and words of the psychiatrists themselves. We must have the best men available in a subject of such vital importance and so far little understood. No doubt we have these men available, and rightly acclaim them, in the leading figures of international psychiatry, and also in the very first-class men that we ourselves possess.

Everyone must heartily agree with Dr. D. W. Winnicott (June 29, p. 998) that the "... real source of good citizenship is in the life of the child in his own home," but would disagree with Dr. Ellis Stungo as to how this is to be attained. And if indeed we have the wrong leaders Dr. Winnicott may be perfectly correct when he asks—and it is a question that must be answered—"why is it that when we start planning we so easily start on the wrong foot?"

I most certainly agree with Dr. Michael Fordham (July 13, p. 62) that teachers should be left to their own jobs; and there

was never anything more true than Dr. Fordham's words, "it is useless to talk on the subject [of behaviour] unless they themselves are good citizens." Otherwise and in plain English it is just hot air and a pure waste of time of all concerned.

Psychiatrists undoubtedly, and rightly so, must play their share like everyone else in building the new world, but they, like other leaders, must be carefully selected. By all means let us all pool our knowledge and learn from each other. But before that I would suggest that it would be beneficial for some of our psychiatrists to sit for a long time in humility (for that is the true essence of greatness and character) before the teachers and other responsible leaders who have already proved themselves and their worth, and who have "stability, character, intelligence, aptitude, freedom from prejudices, and rigid social, political, or religious attitudes," before attempting to plan for the new world.—I am, etc.,

Leyton, E.10.

A. LIONEL ROWSON.

* This correspondence is now closed.—ED., B.M.J.

London College of Osteopathy

SIR,—The question whether medical men should or should not study osteopathy does not, it seems to me, depend upon whether the basic principles agree with our—notoriously fickle—theories but upon whether it works. And I myself, in common with thousands of sane people, medical or not, have indubitable proof that osteopaths will frequently cure or relieve conditions which orthodox practitioners have either failed to cure, or consider incurable, or for which unnecessarily drastic treatments and anaesthetics are used. In short, medicine and surgery can learn something from osteopathic methods which will be of benefit to our patients.

The neat circular of the London College of Osteopathy is a decent and dignified statement of their case, and does not claim to oust medicine, surgery, pathology, and the rest from their place. It is not a substitutional, but an additional, form of therapy. Admittedly, part of the reason why the grocer's boy or the untrained "nature" healer can dub himself an osteopath with impunity is the fault of the osteopaths for not in the past presenting an objective case. But the fact that the medical profession has turned up its nose at the method is responsible for driving many people into the hands of the unregistered—and, in view of the present lack of control, of the unskilled and incompetent. Thus I suggest directly the contrary to what Mr. Tucker (July 27, p. 141) wishes: that the medical man should disarm the unregistered practitioner *not* by ignoring what is good in his methods (and skilful osteopathy *is* good, and is carried out by men as fully trained as our American colleagues in the profession) but by incorporating them in the field of therapy. We should hear much less, then, of the real quacks, and, besides, confound those who—with some justice—charge the medical profession with obscurantism where new methods are concerned.—I am, etc.,

London, S.W.3.

L. J. BENDIT.

Book-reviewing

SIR,—A review of any book should indicate whether in the opinion of the reviewer the book is informed and accurate. In books on specialist topics a fellow specialist is the best judge, and his specialist standing does not imply that he is necessarily a worse critic of style and presentation. Unfortunately, however, a specialist usually has social contacts with his fellows, and adverse criticisms may therefore lead to some degree of ill-feeling, since scientists have no greater ability to separate reason and emotion than other people. Thus the practice of leaving reviews unsigned is, I think, a good one.

Some of your correspondents imply that anonymous contributions are less authoritative than signed ones. This should not be so—anonymous contributions in any journal should have all the authority that the journal itself commands. The better the journal the better the talent at its command. Reviews should have equal authority with the leading articles, which are still almost universally anonymous. The growing habit of printing the names of correspondents and critics lessens the responsibility of the editor, who increasingly becomes a nonentity. This may be good enough for *Punch*, but I hope it will not be good enough for the *British Medical Journal*.—I am, etc.,

London, W.1

PETER C. WILLIAMS.

Dried Sera as Controls

SIR,—It is a standard immunological technique to include in a series of antibody determinations a serum of known potency. On general principles this would be especially necessary in the Wassermann reaction, which involves so many variables. It is generally agreed that known positive and negative sera should be included with each batch of tests, but it is sometimes difficult to ensure that these sera are available when required. It was considered that freeze-dried positive sera of known potency might form a useful standardized reagent for this purpose.

Positive sera were obtained from two known syphilitics and the serum distributed in 0.5 ml. amounts in small glass tubes, dried from the frozen state, sealed in an atmosphere of dry nitrogen, and stored in the refrigerator. Immediately before use the serum was reconstituted by the addition of 0.5 ml. distilled water. These sera have been used by us during the past twenty months and have been found to be stable and to act as useful controls in the Wassermann reaction. There appeared to be a slight loss in complement-fixing antibody during the first month, but no further loss in potency was detected during the test period.

It would be a considerable help in controlling and correlating results if dried standard sera for complement fixation tests were available. Similar sera may prove of value in other complement fixation tests—e.g., for *N. gonorrhoeae*, *Br. abortus*, and *M. tuberculosis*, where known positive sera are less readily available.—We are, etc.,

H. PROOM.

Wellcome Research Laboratories,

The Population of India

SIR,—Dr. B. H. Kirman (June 8, p. 890) finds it "fantastic, inhuman, and unscientific to describe India's problem as an excess of population," but no one with knowledge can deny that *the relation between the population and the food supply* is a real problem. The Government, by means of imports, distribution, rationing, and price control, has done much to avoid widespread famine and disaster, but what I tried to point out in my letter (May 25, p. 811) was the fact that the disproportion between the food supply and the size of the population is realized acutely when seen in particular cases. I come across the problem daily in my medical practice, children being brought for medicine when their immediate and vital need is food. I quoted in my letter one such case, where the birth of the fifth child so strained the family resources that it was directly responsible for the death of the previous two, and I could quote many such cases. For instance, another patient, aged 10, weighs 29 lb. (13.2 kg.), and her younger brother, due to calcium deficiency, has rickets even in a land of abundant sunshine. They are members of a family of five children whose father earns Rs.30–Rs.40 (£2 5s.–£3) per month.
